Design and synthesis of macrocyclic scaffolds for compounds with potential antituberculosis/antibacterial activity and improved CYP450 properties

Graphical Abstract

2nd International Electronic Conference on Medicinal Chemistry 1-30 November 2016

Abstract:

Based on an earlier suggested general pharmacophore approach, compounds active against both tuberculosis virulent strain *H37Rv* and *Staphylococcus Aure*us were obtained. The main drawback of these compounds was an almost complete CYP 3A4 inhibition, which presumably could be overcome by macrocyclization. Two 15-16-membered macrocyclic scaffolds with pharmacophore groups located in appropriate positions were designed and synthetic schemes for their achievement were elaborated. Testing of these compounds against CYP450 enzymes confirmed generally lower inhibition of key cytochromes CYP 3A4 and CYP2D6 by suggested macrocyclic compounds compared to acyclic prototypes. New macrocyclic compounds retained the ability to inhibit *Staphylococcus aureus* growth. The best compound XI showed low CYP450 inhibition and significant (77.2%) inhibition of *Staphylococcus aureus* growth.

Keywords: antibacterial, pharmacophore, Serine/Threonine kinase, cytochrome

3

Introduction. Serine/Threonine kinases

- Serine/Threonine kinases are found in both eukaryotes and prokaryotes
- Among 500+ human protein kinases at least 125 of them are serine/threonine kinases (STK).
- Eukaryotic-like serine and threonine kinases (eSTKs) were found in *Bacillus subtilis, Staphylococcus aureus, Corynebacterium glutamicum, Streptomyces coelicolor, Mycobacterium tuberculosis* and *Streptococcus pneumoniae*

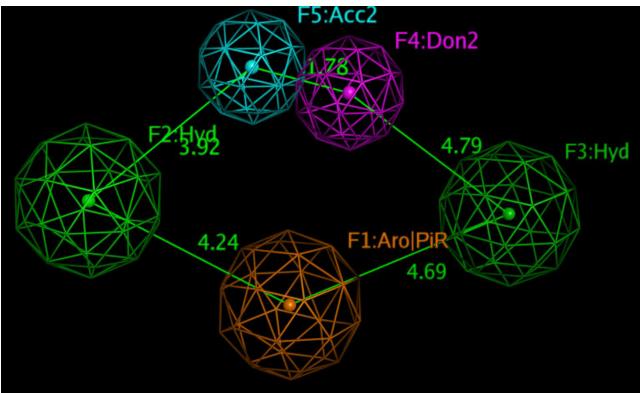

2nd International Electronic Conference on Medicinal Chemistry 1-30 November 2016

Introduction. General pharmacophore for Ser/Thr kinase inhibitors

Previously a concept of general pharmacophore for Ser/Thr kinase inhibitors was developed (N. I. Vasilevich, E. A. Aksenova, D.N. Kazyulkin, and I.I. Afanasyev, *Chem.Biology & Drug Design*, DOI: 10.1111/cbdd.12733, (2016)).

Hydrophobic areas are shown in green, aromatic cycle – in brown, projection of hydrogen bonds acceptor – in blue, and projection of hydrogen bonds donor – in pink

Results and discussion. Activity of selected compounds

- Compounds of both scaffolds showed activity against H37Rv and Staphylococcus Aureus
- Main drawback of these compounds is almost complete inhibition of key cytochrome CYP3A4
- Macrocyclization often helps to improve ADME parameters such as solubility, permeability, selectivity, CYP450 inhibition etc. (*Future Med. Chem.*, 2012, 4(11), 1409–1438; *J. Med. Chem.*, 2011, 54, 1961–2004; *J Comput Aided Mol Des*, 2012, 26,437–450)
- Possible way to improve CYP3A4 is closing compounds of scaffolds A and B into macrocycle

2nd International Electronic Conference on Medicinal Chemistry 1-30 November 2016

Results and discussion. Design of macrocyclic scaffolds

- Geometry of scaffolds A and B allows to close them to 15-16 macrocycle
- Scaffolds C and D contain all pharmacophore elements including three aromatic cycles and donor of hydrogen bond in proper position

Parent acyclic compounds Compounds of Scaffold C

Compounds of Scaffold D

2nd International Electronic Conference on Medicinal Chemistry 1-30 November 2016

Results and discussion. CYP450 inhibition and growth of S.Aureus

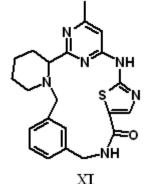

- In most cases macrocyclization improved the inhibition of key cytochromes CYP3A4 and CYP2D6.
- Scaffold C seems to be preferable compared to Scaffold D in terms of CYP 450 inhibition, however, the difference is not essential.
- Macrocyclic compounds were able to inhibit the growth of *Staphylococcus aureus* though with reduced potency.
- Scaffold C is preferable compared to Scaffold D in terms of Staphylococcus aureus growth inhibition

Conclusions

- Two macrocyclic scaffolds for compounds with potential antituberculosis/antibacterial activity were design
- Synthetic schemes aimed at 15-16 member macrocyclic compounds belonging to these scaffolds were developed
- New macrocyclic compounds demonstrated improved CYP3A4 and CYP2D6 inhibition simultaneously retaining the ability to inhibit Staphylococcus aureus growth.
- The best compound XI showed low CYP450 inhibition and significant (77.2%) inhibition of *Staphylococcus aureus* growth.
- Further optimization of designed macrocyclic compounds is required to get safe compounds with high antibacterial activity.
