

Entropy analysis of English n-grams

Objective
★ We estimate the n-gram entropies of English-language texts, using dictionaries and taking into account punctuation, and find a heuristic method for estimating the marginal entropy
★ We propose a method for evaluating the coverage of empirically generated dictionaries and an approach to address the disadvantage of low coverage
★ We compare the probability of obtaining a meaningful text by directly iterating through all possible n-grams of the alphabet and conclude that this is only possible for very short text segments
Methods
☑ Dictionaries of short length texts (n-grams) are
empirically generated on a corpus
☑ Theoretical coverage of empirical vocabularies, where
<i>K</i> is the initial dictionary volume, and <i>k</i> is the number of n-grams that occur once:

Dataset

- Corpus is based on text samples from the **iWeb corpus of** English language
- Contains about **100 million characters** collected from web pages
- Alphabet of corpus includes only **29 characters**: the letters of Latin alphabet, space, dot and comma

Results

- Vocabularies of short English n-grams for length of 10,
- 15, 20, 25 characters (diagram 1)
- Coverage of empirical dictionaries and theoretical volume of saturated vocabularies (table 1)
- Extrapolation results of entropy per character based on a linear system (figure 2)
- Marginal entropy of web English is between 0,65 and **0,8** bits per symbol
- Approximate assessment of number of meaningful ngrams in a language can be found as:

$$\tilde{K}(n) = 2^{H \cdot n}$$

We have estimated the n-gram entropies of natural language texts and examined the number of meaningful texts in English. We have found that the empirical method of generating dictionaries can lead to significant type I errors in estimating the number of meaningful n-grams due to low coverage and eliminated this drawback by offering a method for refining the theoretical volume.

By extrapolating the data with a linear recurrent sequence, we have heuristically determined the limiting entropy of our corpus, which is 0.8 bits per character.
