Abstract: The issues related to the deepening problem of soil salinity constitute an important aspect 14of the protection of the natural environment globally. Therefore, new plant species and innovative 15 solutions supporting the efficient cultivation of plants on saline lands are sought. The research 16 aimed to assess the effect of a quercetin water dilution used in various concentrations on the photo-17 synthetic apparatus performance of Andropogon gerardi plants grown under salt stress. The foliar 18 application of the aqueous quercetin solution significantly changed the relative chlorophyll content 19 in the green part of leaves, the chlorophyll fluorescence parameters, and the gas exchange parame-20 ters. 21

Keywords: Andropogon gerardi; salt stress; quercetin; gas exchange; chlorophyll content; chlorophyll22fluorescence23

1. Introduction

Due to the need to reduce greenhouse gas emissions, with particular emphasis on 26 CO₂, plants produced for special energy purposes are increasingly important in the share 27 of renewable biomass energy, and renewable fuels obtained from biomass can reduce our 28 dependence on fossil fuel resources and reduce greenhouse gas emissions [1]. Big 29 bluestem (Andropogon gerardi) is a perennial prairie grass with C4 photosynthesis type. Big 30 bluestem biomass is intended for direct combustion or processing into briquettes or pel-31 lets. It is also a valuable raw material suitable for fermentation and biogas production [2]. 32 Energy crops should be characterized by efficient conversion of solar radiation energy 33 into biomass, as well as a high dry matter content. Therefore, lignocellulosic biomass, in-34 cluding special energy crops such as big bluestem, can effectively supplement the pro-35 duction of biofuels because they require low production inputs and less competition with 36 food production [3]. In addition, plantations of energy crops allow the management of 37 areas excluded from typical agricultural production: wasteland, marginal land, or land 38 degraded by salinity, which is one of the main threats to agricultural productivity [4,5]. It 39 affects metabolic processes in plants, and their level of tolerance and the accommodation 40 to stress varies depending on the species and cultivar. Crops treated by stress factors react 41 by starting up their defense systems. Any visible symptoms are not observed on the first 42 levels of stress, but the physiology of these plants may change significantly [6,7,8,9]. Ge-43 netic self-defense ability is not sufficient to protect plants at a sufficient level. Therefore, 44

59

for protection and stimulation, various chemical compounds are used more and more of-45 ten. Quercetin (Q) is one of the flavonoids found in plants in the form of glycosides. One 46 of their most important function is to ensure communication with the environment and 47 save plants from photosynthetic stress ROS, which can damage cell DNA, by protecting 48 antioxidant activity [10, 11, 12]. There is little information about the use of Q in plant pro-49 duction, therefore an attempt was made to determine whether it can act as a biostimulator 50 and positively affect the physiological characteristics and growth of plants, including en-51 ergy plants. This study aimed to evaluate the result of the water solution of Q used in 52 various concentrations (1%, 3%, and 5%) on the efficiency of the big bluestem photosyn-53 thetic apparatus cultivated under salt stress. The research hypothesis assumes that Q can 54 be successfully used as a biostimulant and positively influence plant growth. Foliar spray-55 ing Q had a positive effect on the physiological parameters of big bluestem plants grown 56 under salt stress and did not adversely affect the plant status while allowing for a higher 57 yield of green mass, which could be used for energy purposes. 58

2. 4. Materials and Methods

The experiment was performed in vase experiments laboratory at the University of 60 Rzeszów (Poland). Big bluestem seeds were sown in pots with a diameter of 15 cm, in a 61 clay-sand particle size composition soil with a light-acidic pH (pH: 1M KCI=6.35; 62 H₂O=6.52). The experiments were conducted in growth chambers (Model GC-300/1000, 63 JEIO Tech Co., Ltd., Seoul, South Korea) at a temperature of 23±2° C, humidity 60±3% RH, 64 photoperiod 16/8 h (L/ D), and the maximum light intensity of about 300 μ mol·m⁻²·s⁻¹. The 65 substrate humidity was set as the substrate humidity level was set as 60% of the field 66 water capacity. The experiment was carried out in four replications - 10 pots per variant 67 (n=80), the positions of the pots in the experiment were randomized every 5 days. After 68 emergence, the density of the experiment was set at 3 plants in one pot. In the two-leaf 69 phase, the plants were watered with a 220mM water dilution of sodium chloride (NaCl). 70 Plants not treated with NaCl were used as controls. 20 and 27 days after emergence, the 71 plants were sprayed with an aqueous solution of derivative Q at concentrations of 1.0%, 72 3.0%, and 5.0% at 50 ml per pot by completely covering the plant's surface. On the controls 73 sample, deionized water was used in the same volume. 74

Measurements of physiological processes: the net photosynthetic rate (PN), transpiration rate (E), stomatal conductivity (g_s) and intercellular CO₂ concentration (C_i)), the relative chlorophyll (CCI) content, and chlorophyll fluorescence (the maximum quantum yield of photosystem II (PSII) (F_v/F_m), the maximum quantum yield of primary photochemistry (F_v/F_0) and the photosynthesis yield index (PI)) were performed four times on the first or second fully developed leaves: on the next day and seven days after each treatment following the methodology presented by Migut et al. [13].

Statistical analysis was made using TIBCO Statistica 13 (TIBCO Software Inc., Palo82Alto, CA, USA). A repeated-measures ANOVA (with time assessment as a factor) was83then performed. Tukey's post hoc test was performed with the significance level $p \le 0.05$ to84determine and verify the relationship.85

3. Results and Discussion

3.1. Gas Exchange Measurement

The first plants' response to abiotic stress is the closing of the stomata [14]. Antioxi-88 dants, including quercetin, belong to the group of organic compounds which, through 89 osmotic regulation, may play an important role in alleviating stress related to environ-90 mental factors, like salinity [15,16], and have a positive impact on the gas exchange pro-91 cess. In this research, it was found that the highest concentration of Q used (5%) had the 92 most favorable effect on P_N, E, and g_s. Smaller differences in the values of the analyzed 93 parameters were observed with the passage of time. The strongest plants response to the 94 spraying application of Q was observed in the first and second measurement periods. A 95

lower increase in the analyzed parameters was observed after the next application of Q. It 96 may suggest that the first dose of the derivative has a strong stimulatory effect, and the 97 subsequent dose may support the beneficial Q effect. The increase in g₅, seen by the quer-98 cetin derivative, lowered the intracellular CO₂ accumulation in the mesophyll and caused 99 a reduction in Ci values. This phenomenon was associated with an increase in PN intensity; 100 therefore, it seems warranted to determine a single dose of quercetin in the environmental 101 stress presence. The concentration of C_i increases with longer exposure to stress factors, 102 which indicates a reduction in the ability to bind CO2 in the Calvin-Benson cycle, and thus 103 a significant reduction in photosynthesis efficiency may indicate degradation of the pho-104 tosynthetic apparatus [17]. 105

measurement times; Capital letters: Significant differences between the averages of the measurement dates for the concentrations (p < 0.05). 113

3.2. Chlorophyll Fluorescence

Photosynthesis is related to all plant cell metabolic and physiological processes, and environmental changes modifying them will have an impact on the photosynthetic process. Nutrient deficiency and abiotic stresses occurring during plant vegetation directly affect the photosynthetic apparatus [18, 19]. The parameters of chlorophyll fluorescence in big bluestem plants were stimulated by the foliar application of the aqueous solution of Q. The increase in the value of these parameters was related to the increasing concentration of Q and the duration of the experiment.

Figure 2. Effect of different aqueous concentrations of Q on Chl fluorescence parameters in the big125bluestem leaves (A) F_v/F_m , (B) F_v/F_0 , (C) PI. Lowercase: significant differences between the averages126of the respective measurement times; Capital letters: Significant differences between the averages127of the measurement dates for the concentrations (p <0.05). 3.3. Relative Chlorophyll Content</td>128

Chlorophyll, reflecting the health condition of plants is one of the most important 129 biochemical features connected with the availability of water and the level of plant nutrition [20,21]. Reduction of it is content in plants subjected to abiotic stress may result from 131 the breakdown of thylakoid membranes, which is more degraded than the synthesis of 132 chlorophyll through the formation of proteolytic enzymes. The use of an aqueous solution 133 of Q positively influenced the growth of the relative content of Chl in big bluestem leaves. 134

114

122

123

Aqueous Q solution can stimulate and improve plant tolerance to abiotic stresses by 135 strengthening antioxidant enzymes and preserving photosynthetic activity, as well as pre-136 venting membrane peroxidation or strengthening the plant's defense system against oxi-137 dative damage. 138

Figure 3. Effect of different aqueous concentrations Q on CCI in big bluestem leaves. Lowercase: 140 significant differences between the averages of the respective measurement times; Capital letters: 141 Significant differences between the averages of the measurement dates for the concentrations (p 142 <0.05). 143

4. Conclusions

An aqueous solution of Q used in the presented experiment positively affected the physiological 145 properties of big bluestem plants and at the same time, no deterioration of their condition was ob-146 served. The most stimulating effect on the course of physiological processes had the 3% and 5% 147 solutions. There was an increase in PN, E, gs, CCI, Fv/Fm, Fv/F0, and PI values and a decrease in Ci 148 values. The conducted research may contribute to increasing the yield of the above-ground mass of 149 big bluestem plants, and thus increasing the profitability of establishing and running a plantation. 150 In addition, these results can be used as a prime study for developing a strategy to reduce the neg-151 ative impact of abiotic stresses on the productivity of agriculture, including crops intended for en-152 ergy purposes. Foliar application of Q can be used as an effective and environmentally friendly way 153 of limiting soil salinity impact on crops and initiating the development of resistance of big bluestem 154 plants to stress, and lead to an increase in the potential and stability of its yield. 155
