Keywords: urinary tract infection; etiology; antimicrobial resistance

Introduction: Urinary tract infections (UTIs) are one of the most common infections both in the community and in the hospital setting. Aim: The aim of this study is to investigate the etiological spectrum and antimicrobial resistance of most frequently isolated pathogens, associated with UTIs in ambulatory patients in Varna city, Bulgaria during a seven-month period (October 2020–April 2021). Materials and methods: A total of 1600 urine samples, collected from patients with suspected UTIs were tested. Screening for bacterial growth was done by HM&L Uroquattro instrument (ALIFAX, Italy). Species identification and antimicrobial susceptibility testing were performed by VITEK 2 Compact System (bioMerieux) and Kirby-Bauer disk diffusion method. Results: A total of 127 urine samples (7.9%) were positive for bacterial growth by HM&L. From these samples, 127 bacterial pathogens were isolated: Gram negative bacteria were found in 62.2% (n = 79) and Gram positive—in 37.8% (n = 48). E. coli was the predominant species, associated with UTIs in the studied group of patients (77%, n = 61). The Gram-positive bacteria accounted for 37.8% (n = 48), with E. faecalis being the leading pathogen in this group (87.5%, n = 42). Staphylococcus saprophyticus and Streptococcus agalactiae were diagnosed in 8% (n = 4) and 4% (n = 2) respectively. The resistance rates in the group of Gram-negative isolates (n = 79) in decreasing order were as follows: ampicillin, 64.5% > trimethoprim/sulfamethoxazole, 35.4% > ciprofloxacin, 29.1% > amoxicillin-clavulanic acid, 27.8% > cefuroxime, levofloxacin, 21.5% > fosfomycin, 12.6% > ceftixime, 13.9% > ceftazidime, 10.1% > gentamicin, nitrofurantoin, 6.3% > nitroxoline, 5%. The resistance rates among the isolates of E. faecalis (n = 42) were as follows: ciprofloxacin, 28.6% > gentamicin, 23.8% > levofloxacin, 19% > nitrofurantoin, 4.7% > amoxicillin, 2.4%. A low rate of 3rd generation cephalosporin resistance (ceftazidime, cefotaxime, ceftiraxone) is detected among the representative of order Enterobacteriales in the study. The rates of ESBL-producing isolates, confirmed by the phenotypic DDST, were as follows: 5% in E. coli (n = 4), 2.5% in K. pneumoniae (n = 2) and Enterobacter cloacae (n = 2). No resistance to meropenem, amikacin, vancomycin and teicoplanin was found in the studied collection of isolates (n = 127). Conclusion: The etiologic spectrum of UTIs in ambulatory patients was dominated by E. coli, followed by E. faecalis. In the group of Gram-negative uropathogens, high resistance rates to ampicillin, trimethoprim/sulfamethoxazole and quinolones were detected. Third generation cephalosporins, fosfomycin, nitrofurantoin and nitroxoline retained very good activity.
Among *Enterococcus faecalis* isolates, the second most commonly isolated bacterial species, a decreased activity of quinolones was found too, but the aminopenicillins and nitrofurantoin remain highly active.
