Abstract: Condensation of chlorides of substituted pyrazine-2-carboxylic acids with ring substituted anilines yielded a series of anilides of 6-chloropyrazine-2-carboxylic, 5-(1,1-dimethylethyl)-pyrazine-2-carboxylic or 6-chloro-5-(1,1-dimethylethyl)pyrazine-2-carboxylic acids. Products were tested for their photosynthesis-inhibiting activity. The most active inhibitor of oxygen evolution rate in spinach chloroplasts was 3,5-bis(trifluoromethyl)anilide of 6-chloropyrazine-2-carboxylic acid (IC₅₀ = 0.026 mmol dm⁻³), the most active antialgal compound was 3-methylanilide of 6-chloro-5-(1,1dimethylethyl)pyrazine-2-carboxylic acid (IC₅₀ = 0.026 mmol dm⁻³). The elimination of phenolic group in the benzene moiety led to an decreased photosynthesis-inhibitory activity.

Keywords: Anilides of 6-chloro-5-alkylpyrazine-2-carboxylic acids; Photosynthesis inhibition; Spinach chloroplasts; *Chlorella vulgaris*.

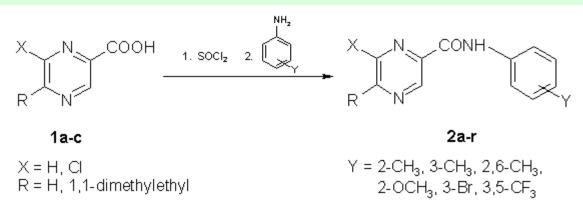

Introduction

Various compounds possessing -NHCO- group, *e. g.* acyl and thioacyl anilides, benzanilides, phenyl carbamates, etc., were found to inhibit photosynthetic electron transport [1--4]. Anilides of 2-alkylpyridine-4-carboxylic [5,6], 2-alkylsulfanyl-4-pyridinecarboxylic [6,7] acids inhibited oxygen evolution rate in *Chlorella vulgaris* and their inhibitory activity depended on the lipophilicity of the compounds. Several esters of alkoxy substituted phenylcarbamic acids (APA) showed the antialgal activity against *Chlorella vulgaris* [8--10]. The inhibitory efficiency of APA concerning chlorophyll production in *Chlorella vulgaris* depended on the lipophilicity of the alkoxy substituent and also on its position on the aromatic ring [8--10]. The antialgal activity of APA correlated with the antifungal activity of these compounds against *Candida albicans* [10]. We have recently reported the synthesis of a series of anilides prepared from some or 5-alkylpyrazine-2-carboxylic acids and some aminophenols [11].

The presented study is concerned in the synthesis of another series of anilides prepared from substituted pyrazin-2carboxylic acids and alkylated, resp. alkoxylated (2-, 3-methyl; 2,6-dimethyl, 2-methoxy) or halogenated (3-bromo; 3,5-bis(trifluoromethyl)) anilines. The aim of this work is to search for the structure--activity relationships and to determine the importance of increased hydrophobic properties for photosynthesis-inhibiting evaluation of newly prepared pyrazine-2-carboxylic acid anilides.

Results and Discussion

The synthesis of anilides is shown in Scheme 1. Condensation of chlorides of 6-chloropyrazine-2-carboxylic (1a)[12], 5-(1,1-dimethylethyl)pyrazine-2-carboxylic (1b) [11] or 6-chloro-5-(1,1-dimethylethyl)pyrazine-2-carboxylic (1c) [11] acids with ring substituted anilines yielded a series of 18 anilides of mentioned substituted pyrazine-2-carboxylic acids 2a-r.

Scheme 1: Preparation of anilides of substituted pyrazine-2-carboxylic acids 2a--r.

The melting points, yields, and elemental analyses for the compounds prepared are given in Table 1, and the IR and ¹H NMR spectral data in Table 2. Calculated log *P* values of anilides **2a--r** are shown in Table 3.

Biological activity of prepared anilides 2a--r concerning inhibition of oxygen evolution rate in spinach chloroplasts was investigated. The inhibitory activity of the compounds has been expressed as IC₅₀ values (see Table 3). Additionally some inhibition of chlorophyll production in green algae *Chlorella vulgaris* was studied at the anilides 2f, 2l, 2m, 2n, 2o and 2p. Results of their antialgal activity are given in Table 4.

The studied compounds inhibited photosynthetic electron transport in spinach chloroplasts what was reflected in the inhibition of oxygen evolution rate. The IC₅₀ values varied in the range from 0.026 (**2m**) to 1.072 mmol dm⁻³ (**2a**). In general, the photosynthesis-inhibiting activity of the studied compounds depended on their lipophilicity showing a quasi-parabolic course. However, the studied compounds could be divided into two group. The compounds with 2-CH₃ substituent on the phenyl ring (**2a**, **2b**, **2c**, **2p**, **2q** and **2r**) had lower biological activity than the other investigated compounds with comparable log *P* values. Consequently, we assume that the methyl substituent in *ortho* position of the benzene ring is disadvantageous from the viewpoint of interactions with the photosynhetic apparatus. On the other hand, compound **2m** exhibited higher inhibitory activity than expected.

The antialgal activity of six studied compounds (2f, 2l, 2m, 2n, 2o and 2p) showed a quasi-parabolic dependence upon $\log P$ with maximum activity for compounds having $\log P$ in the range from 3.18 to 5.16. With the further increasing of the lipophilicity a dramatic decrease of antialgal activity was observed.

Table 1. Analytical data of the anilides 2a--r.

Experimental

General

Melting points were determined on a Kofler apparatus and are uncorrected. Elemental analyses were obtained using an EA 1110 CE instrument (Fisons Instruments S. p. A., Milan). The IR spectra were recorded on a Nicolet Impact 400 spectrometer in KBr pellets. The ¹H NMR spectra were measured for solutions in CDCl₃ with a Varian Mercury - Vx BB 300 spectrometer operating at 300 MHz. Chemical shifts were recorded as delta values in parts per million (ppm), and were indirectly referenced to tetramethylsilane via the solvent signal (7.26 for ¹H). Multiplicities are given

together with the coupling constants (in Hz). Log *P* values were computed using a program ACD/Log P ver. 1.0 (Advanced Chemistry Development Inc., Toronto).

Synthesis of anilides 2a--r

A mixture of acid (*i. e.* 6-chloropyrazine-2-carboxylic [8], 5-(1,1-dimethylethyl)pyrazine-2-carboxylic [3] or 6-chloro-5-(1,1-dimethylethyl)-pyrazine-2-carboxylic [3] acids, 0.05 mol) and thionyl chloride (5.5 cm³, 75 mmol) in 20 cm³ of dry benzene was refluxed for about 1 h. Excess of thionyl chloride was removed by repeated evaporation with dry benzene in vacuo. The crude acyl chloride dissolved in 50 cm³ of dry acetone was added dropwise to a stirred solution of the corresponding substituted aniline (50 mmol) in 50 cm³ of dry pyridine keeping at the room temperature. After the addition was complete, stirring continued for another 30 min. The reaction mixture was then poured into 200 cm³ of cold water and the crude anilide was collected and recrystallized from aqueous ethanol.

Study of inhibition of oxygen evolution rate in spinach chloroplasts

The oxygen evolution rate in spinach chloroplasts was investigated spectrophotometrically (Specord UV VIS, Zeiss, Jena) in the presence of an electron acceptor 2,6-dichlorophenol--indophenol, by method described in Ref. [13]. The compounds were dissolved in dimethyl sulfoxide (DMSO) because of their low water solubility. The used DMSO volume fractions (up to 5 vol. %) did not affect the oxygen evolution. The inhibitory efficiency of the studied compounds has been expressed by IC_{50} values, *i. e.* by molar concentration of the compounds causing 50 % decrease in the oxygen evolution relative to the untreated control. Comparable IC_{50} value for a selective herbicide atrazine [14] is about 1.0 mmol dm⁻³.

Study of inhibition of chlorophyll production in green algae Chlorella vulgaris

The algae *Chlorella vulgaris* were cultivated statically at room temperature according to Sidoova *et al.* [15] (photoperiod 16 h light / 8 h dark; illumination 4000 lx; pH = 7.2). The effect of compounds **2f**, **2l**, **2m**, **2n**, **2o** and **2p** on algal chlorophyll (Chl) content was determined after 4-day cultivation in the presence of the tested compounds, expressing the response as percentage of the corresponding values obtained for control. The Chl content in the algal suspension was determined spectrophotometrically (Specord UV VIS, Zeiss Jena, Germany) after extraction into *N*,*N*-dimethylformamide according to Inskeep and Bloom [16]. The Chl content in the suspensions at the beginning of cultivation was 0.5 mg dm⁻³. Because of their low water solubility, the tested compounds were dissolved in DMSO. DMSO concentration in the algal suspensions did not exceed 0.25 v/v % and the control samples contained the same DMSO amount as the suspensions treated with the tested compounds.

Acknowledgements. This study was supported by the Grant Agency of Charles University in Prague (Grant No. 26/1998 BCH), by the Scientific Intents of Charles University in Prague (No. 11160001), by the Ministry of Education of the Czech Republic (project No. VS97124), and by the Scientific Grant Agency of the Ministry of Education of the Slovak Republic and the Slovak Academy of Sciences (Grant No. 1/7262/20). We also thank D. Karlickova, J. Zizkova, and T. Vojtisek for their skillful technical assistance and Dr. D. Mikulasova from the Department of Biochemistry, Faculty of Natural Sciences, Comenius University, Bratislava, for her assistance in the preparation of chloroplasts.
