INTRODUCTION & AIM

Proteolysis-targeting chimeras (PROTACs) are heterobifunctional molecules consisting of two linked substructures: protein-of-interest-binding ligand (POI ligand) and the E3 ubiquitin ligase-binding ligand (1). Simultaneous binding of the PROTAC to both the POI and the E3 ligase leads to the ubiquitylation of the POI, thus marking it for degradation via the ubiquitin proteasome system (1). First fully-synthetic PROTAC was synthesised in 2001 (2). Since then, an expansion in PROTAC synthesis is seen, though challenges are present in their design, synthesis and application in therapy. In particular, the **evaluation of pharmacokinetic and pharmacodynamic properties of PROTAC molecules is quite difficult** due to their catalytic nature (3). Additionally, they have high molecular weight and they exhibit hooking effect (4,5). To address those issues, scientists started to investigate PROTAC linker characteristics and their impact on the biodegradation efficacy of PROTACs. However, **the impact of linker structure on PROTACs' DMPK properties is still not well understood** (6).

In this poster, I analyse three types of modifications potentially leading to improved bioavailability of PROTACs *in silico*, on an example of EGFR PROTACs' structure. Those modifications include changes to: i) linker length ; ii) linker rigidity; iii) number of hydrogen donors in linker; iv) number of introduced heteroatoms.

METHOD

All PROTACs designed contained brigatinib as EGFR-targeting ligand, and lenalidomide as a ligand targeting cereblon (CRBN) E3 ligase. Brigatinib was chosen due to its effectiveness against C797S/T790M/activating-mutation (triple-mutation) related to osimertinib resistance in treating non-small-cell lung cancer (7). Lenalidomide was chosen due to its ability to create stronger H-bonds at the CRBN–CK1α interface (8).

All compounds were tested in silico for the evaluation of their ADMET properties, using freely available online ADMET Tools: SwissADME, ADMETlab 2.0, pkCSM6. Additionally, tools that involve artificial intelligence (AI) calculations were used, and the results obtained from these softwares were compared to non-AI tools. AI software used: ADMET-AI, Simulations Plus. SMILES strings were obtained using SMILES generator by Cheminfo.org. Obtained results were compared and most interesting findings are shown.

CONCLUSION AND FUTURE WORK

Overall, the AI-powered tools gave more precise measurements. It was noted that the increase in linker length contributed to better bioavailability and the reduction of carcinogenicity of PROTACs. Introduction of more rigid structures contributed to increased plasma protein binding (PPB) rate. Increasing number of hydrogen bond donors contributed to improved aqueous solubility and the decrease in oral acute toxicity, however, it also lowered the rate of gastrointestinal absorption of the drugs. The higher the number of heteroatoms, the lower hERG blocking was apparent. Unfortunately, for most other parameters highlighted in the results, it was not possible to determine the relationship with the modifications set in this paper. As the results were not precise and varied greatly between programmes, it is necessary to perform *in vitro* and *in vivo* tests and determine the drugs' real ADMET properties. So far, the tools seem to not be able to calculate PROTAC's properties with great precision, and are more suitable for small molecules.
