## Introduction

People spend about 90% of their time indoors, where they are constantly exposed to diverse microbial communities. While indoor bacteria significantly impact human health and environmental hygiene, most exist in a dormant state due to low-nutrient conditions.

However, the growth dynamics of these communities about how they respond to nutrient shifts and colonize surfaces remain largely unexplored. Understanding these growth patterns is essential for assessing microbial adaptability and managing indoor ecological safety.

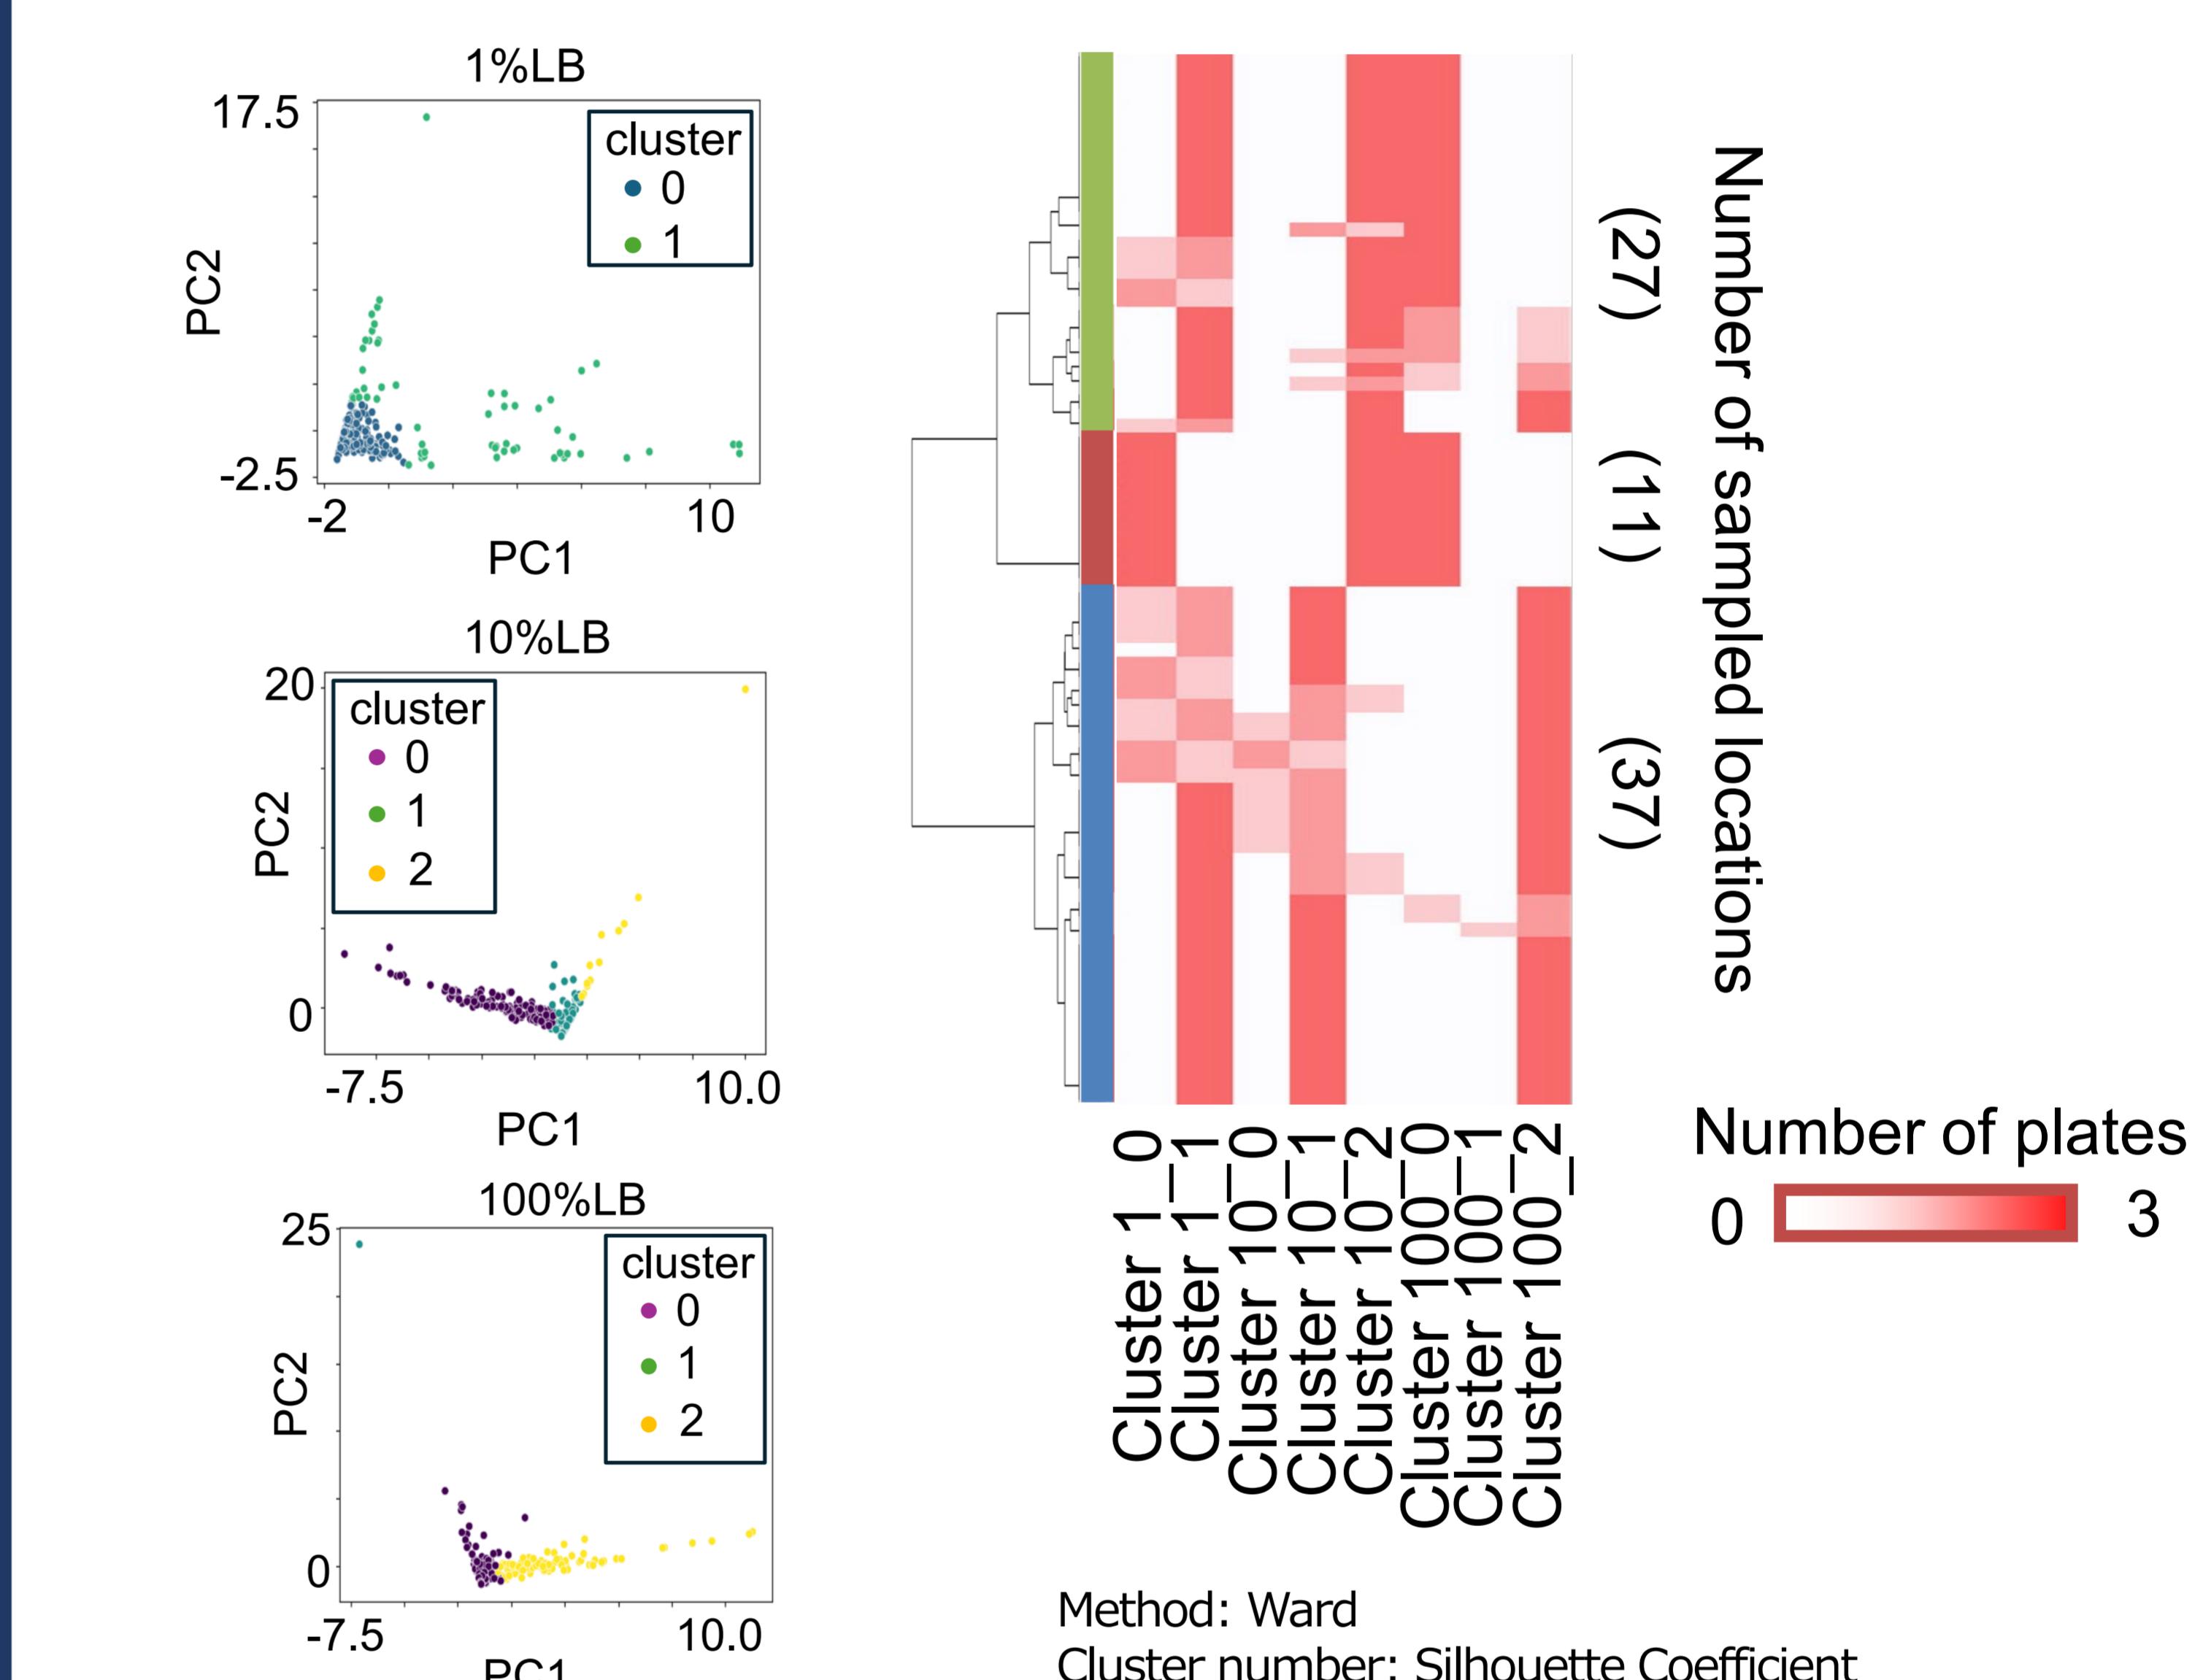

## 1. Acquisition of growth data

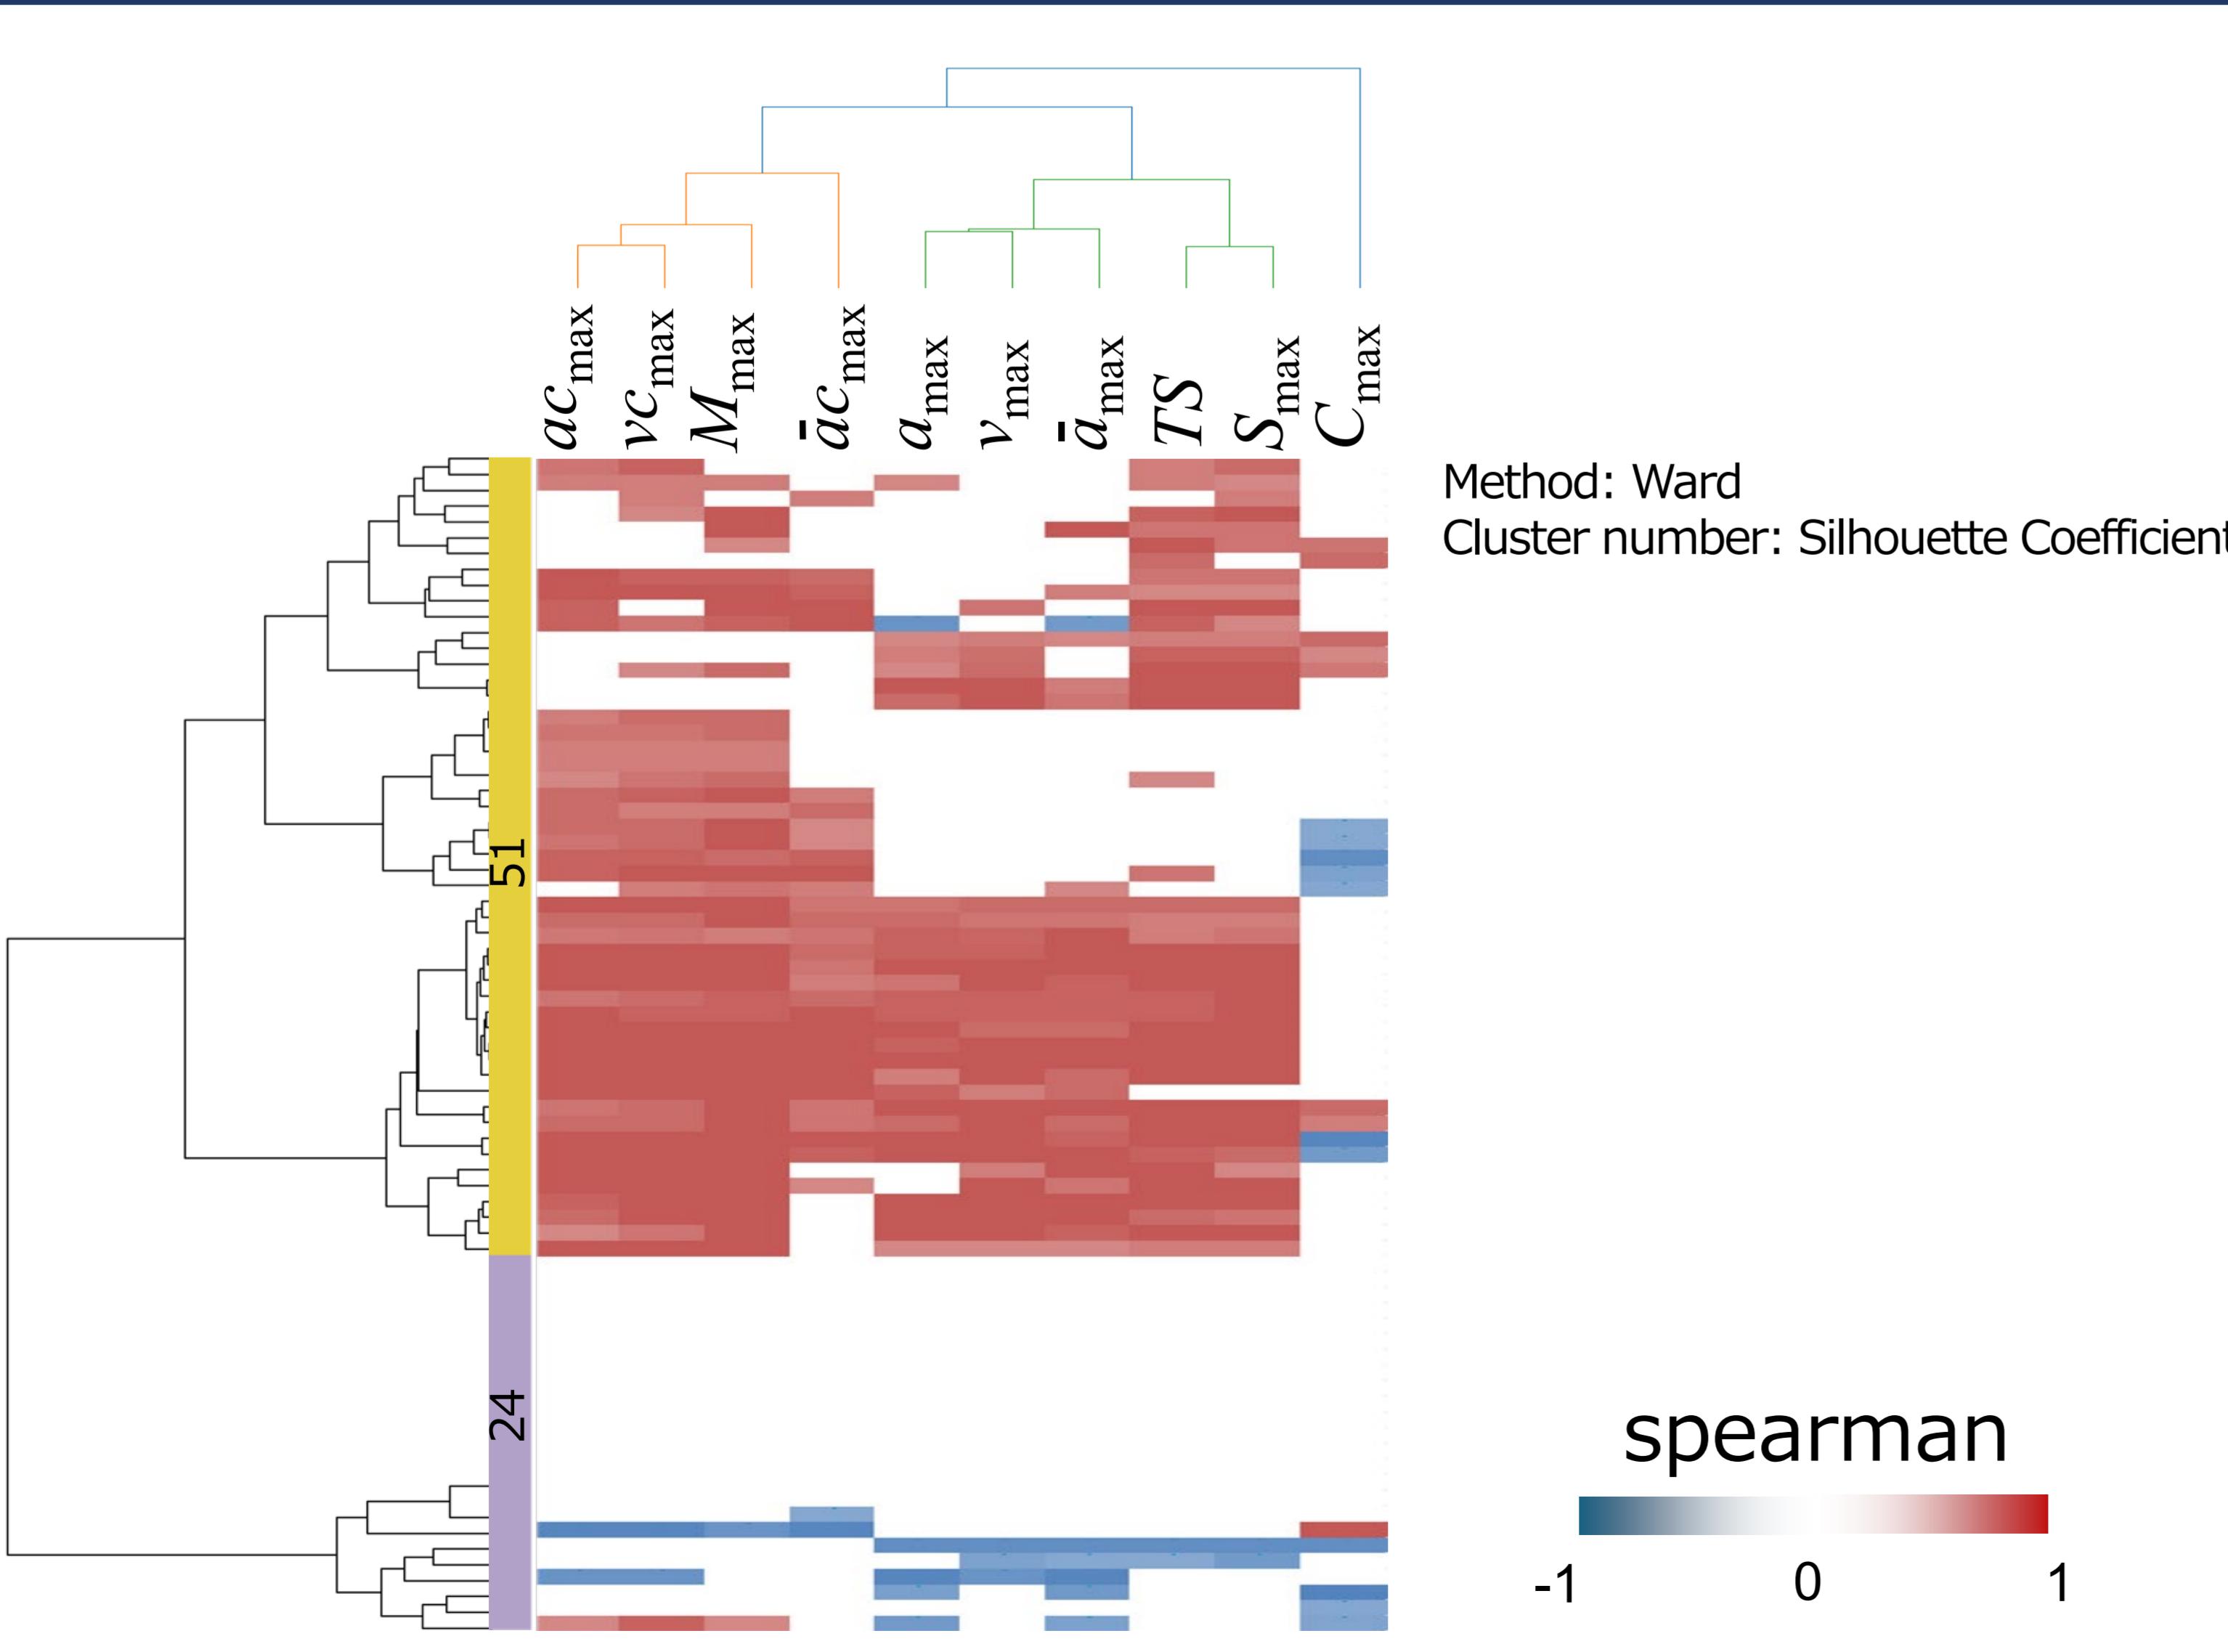

10 parameters were used to estimate the colony growth.

## 2. Clustering by growth

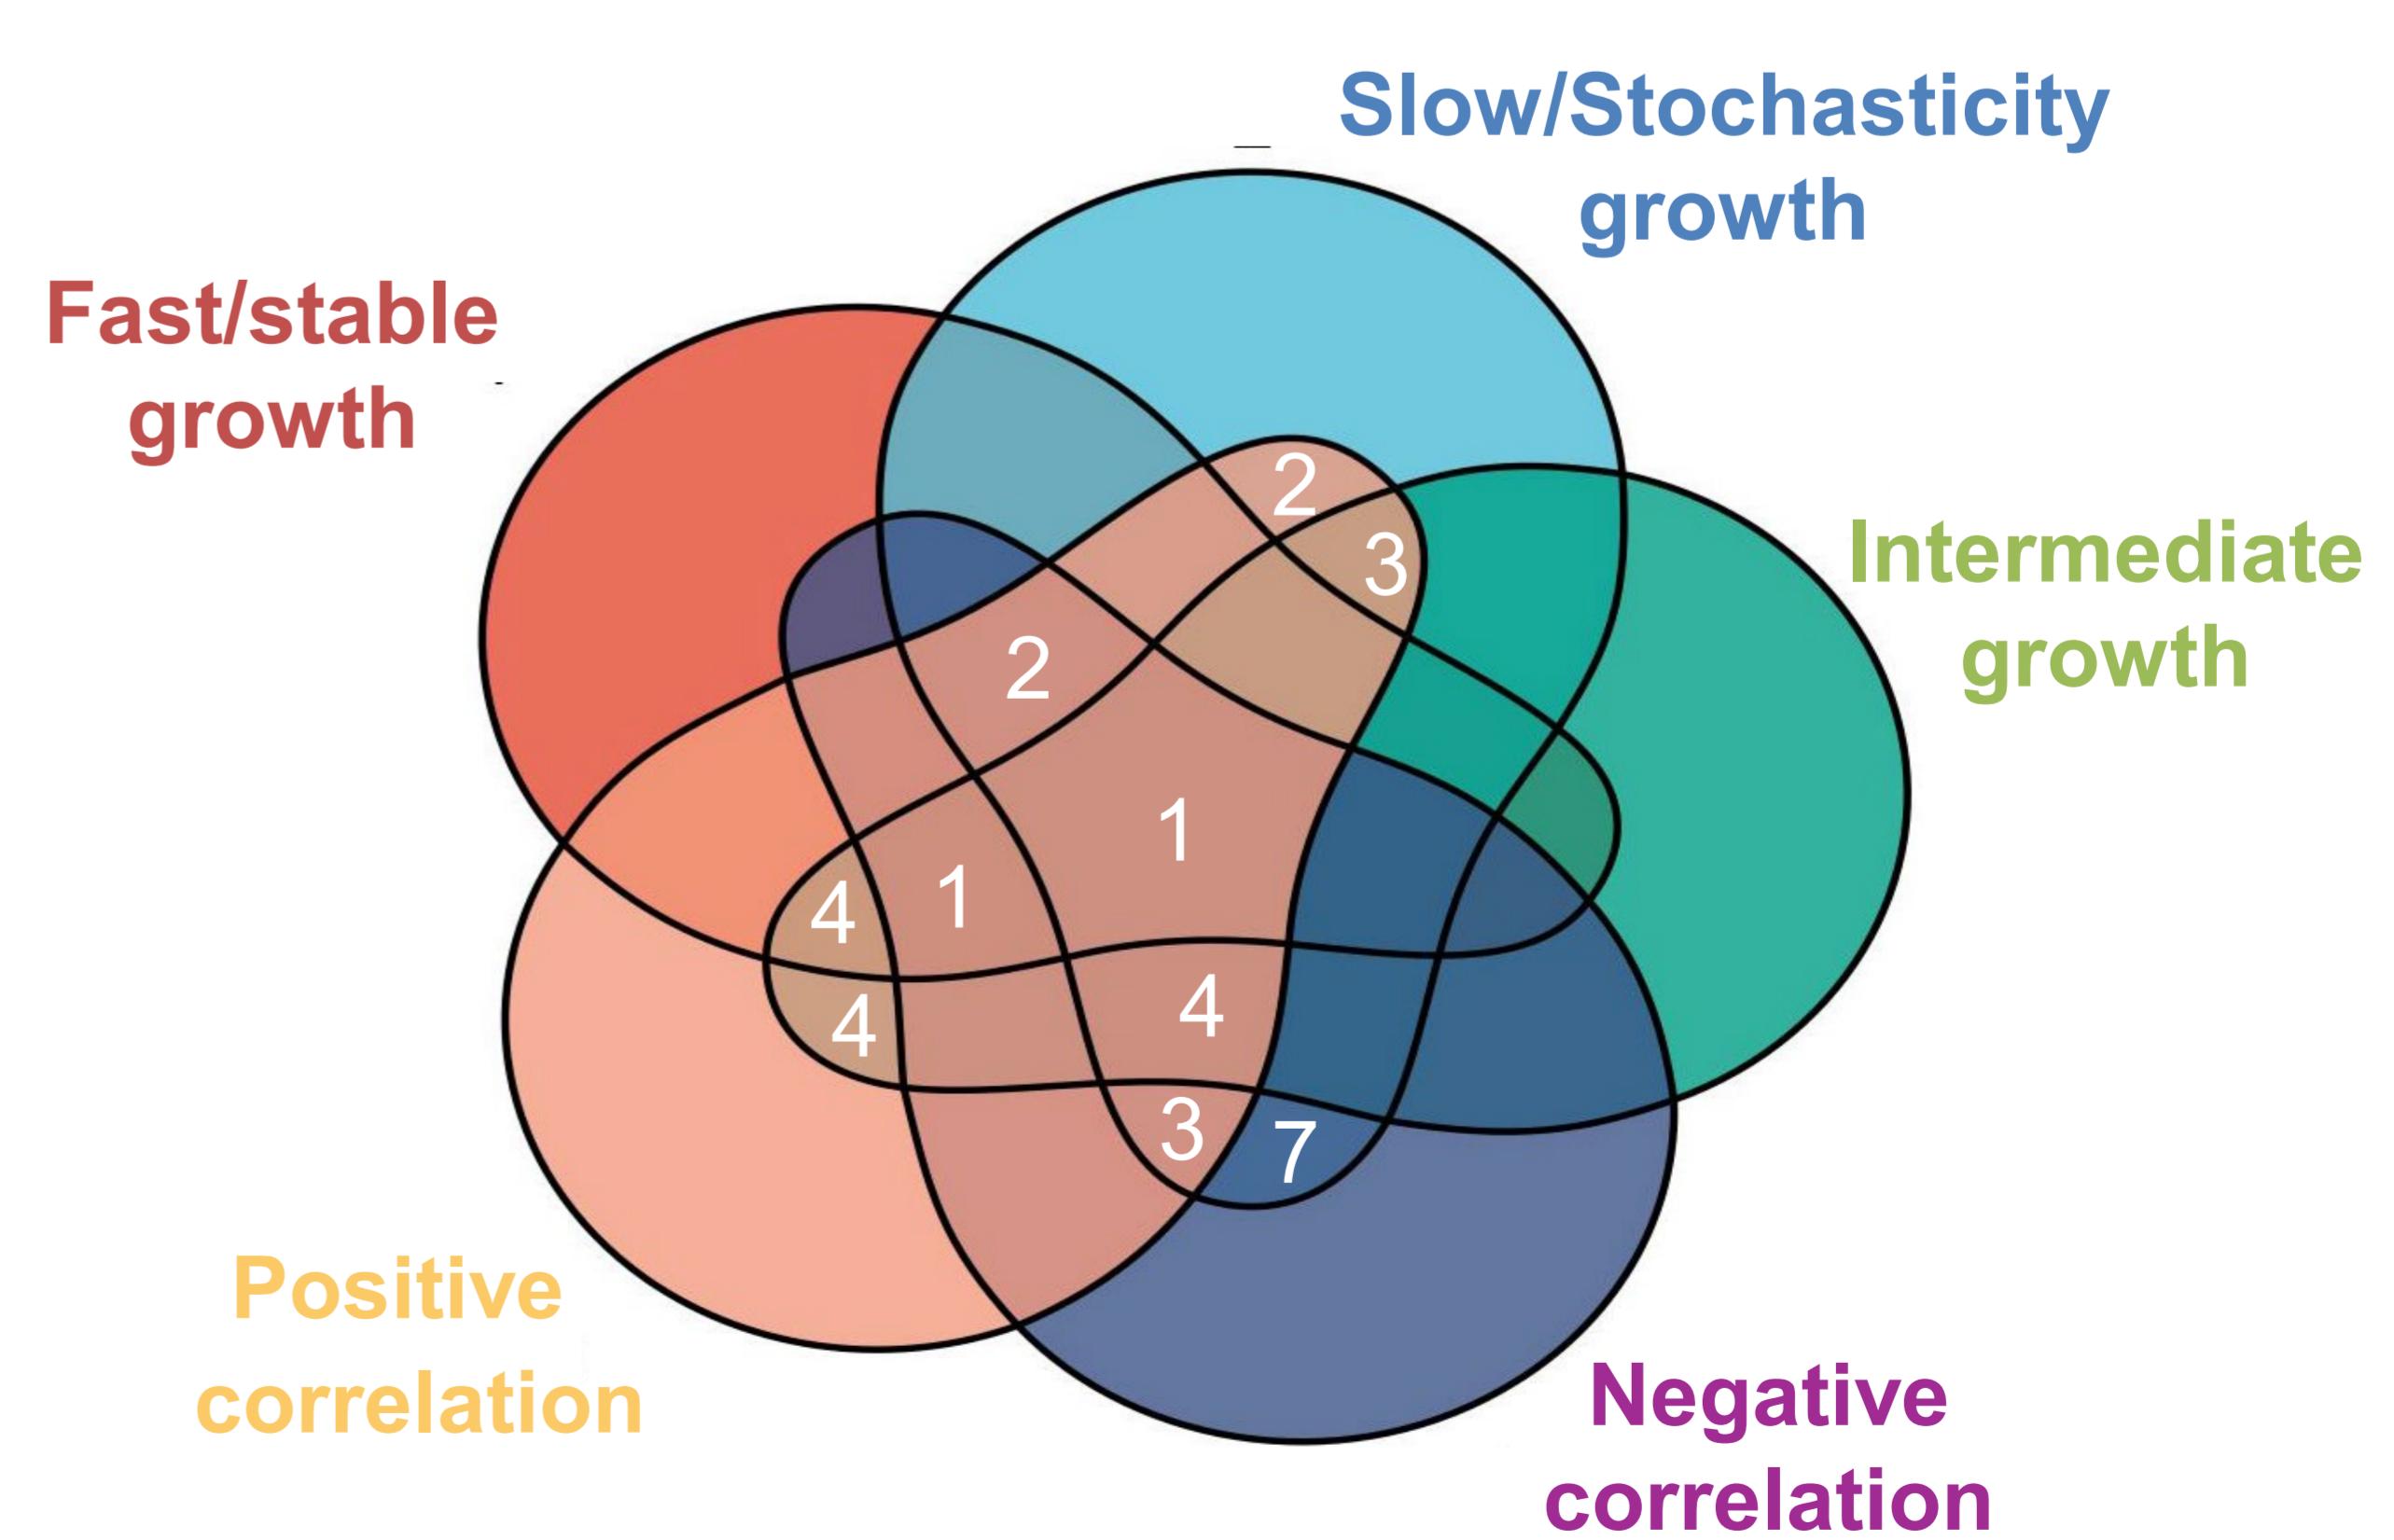

Objects were divided into 3 clusters by growth.

## 3. Growth-Concentration Correlation

Objects were divided into 3 clusters by growth.

## 4. Link growth and nutrient

Most environmental microbial communities exhibit concentration-driven growth plasticity.
