Abstract
Scalar field models are known for their dynamical nature i.e. dynamical equation of state parameter to explain the late-time cosmic acceleration of the universe. Quintessence canonical scalar field with a potential one such field which is introduced to account for the late time acceleration of the universe. In the present work, different kinds of scalar field potentials (under quintessence cosmological model) are mathematically investigated using tracking parameter to examine whether these potentials are showing thawing or tracking behavior. Tracking parameter is considered because during cosmic evolution the dynamics of tracking depends susceptibility on the variation of this particular parameter. Each potential is analyzed using this parameter and accordingly the behavior is shown. It is found that among the four potentials used, three are showing tracking properties and only one is showing thawing property as per the tracking parameter.

Mathematical Background
The four potentials of different forms (power law, exponential and hyperbolic form) are defined as:

- Exponential form: \( V(p) = V_0 p^{\alpha} e^{-\beta p} \)
- Power law form: \( V(p) = V_0 (1 - p^2)^{\gamma} \)
- Hyperbolic form: \( V(p) = V_0 \cosh(p\alpha p) \)

where, \( V_0 , \alpha \) and \( \beta \) are real constants in which \( \alpha \) and \( \beta \) are dimensionless and \( V_0 \) is dimensional. Here, first the analysis is done keeping \( \beta = \beta \) for all values in the range of \( R \). Then, a particular value of \( \beta \ (1 - 1) \) is chosen to study the behavior of these potentials. Further, other values are equally appealing provided they be in a range of \( R \). So, here we considered \( \beta = 1 \) and \( 1 \) respectively, for the potentials described above to proceed further towards its mathematical analysis.

Analysis

a) \( V_0 p^{\alpha} e^{-\beta p} \)

\[ \Gamma = 1 - \frac{(1 - \beta)}{\beta} \]

For \( \beta = 0 \), \( \Gamma \) is undefined. From (1), \( \beta = 1, \Gamma = 1 \).

For \( \beta \) and \( \Gamma \) values of \( \beta = 1 \), \( \Gamma > 1 \).

b) \( V(p) = V_0 (1 - p^2)^{\gamma} \)

\[ \Gamma = \frac{1}{1 - \beta} \]

For \( \beta = 0 \), \( \Gamma \) is undefined. From (2), \( \beta = 1, \Gamma = 1 \).

For \( \beta \) and \( \Gamma \) values of \( \beta = 1 \), \( \Gamma > 1 \).

c) \( V_0 \cosh(p\alpha p) \)

\[ \Gamma = \frac{1}{1 - \beta} \]

For \( \beta = 0 \), \( \Gamma \) is undefined. From (3), \( \beta = 1, \Gamma = 1 \).

For \( \beta \) and \( \Gamma \) values of \( \beta = 1 \), \( \Gamma > 1 \).

d) \( V_0 \cosh(p\alpha p) \)

\[ \Gamma = \frac{1}{1 - \beta} \]

For \( \beta = 0 \), \( \Gamma \) is undefined. From (4), \( \beta = 1, \Gamma = 1 \).

For \( \beta \) and \( \Gamma \) values of \( \beta = 1 \), \( \Gamma > 1 \).

The simplest field mimicking dark energy is a canonical scalar field with a potential known as quintessence. This field is capable of reproducing the late-time accelerated behavior. It has an equation of state given by:

\[ \omega = \frac{\rho}{3H^2} \]

where \( \rho \) is energy density. Quintessence scalar field is broadly classified into two classes:

1) Thawing Models: They are slow roll models which depend on initial value conditions.

2) Freezing Models: They are fast roll models, insensitive to the initial conditions but over the entire range of scalar field, they depend sensitively on the shape of the potential.

\( \Gamma \) is the tracking parameter and the properties of \( \Gamma \) determine whether the tracking solutions exist or not. For any kind of potential \( \Gamma \) can be \( > 0 \) or \( < 0 \).

\[ \Gamma = \frac{\sum_{i=1}^{n} V_i p^{\alpha} e^{-\beta p}}{\sum_{i=1}^{n} V_i (1 - p^2)^{\gamma}} \]

\( \Gamma \) is called the tracking parameter, where \( V_i \) and \( V_i \) are differentiation w.r.t scalar field \( \phi \) and \( V \) is the scalar field potential.

Table 1: Behavior shown by potentials used for quintessence cosmological model

Discussion
It is clearly shown in the table that only three potentials are showing tracking behavior \((\Gamma > 1)\). The potentials showing tracking behavior are basically fast-roll (freezing) potentials. The hyperbolic potential is showing thawing behavior \((\Gamma < 1)\). Let’s discuss their behavior.

- \( \Gamma > 1 \): The potential \( V_0 p^{\alpha} e^{-\beta p} \) is a scaling attractor for \( \Gamma > 1 \) and is basically called slow-roll (freezing) potential. The dominant matter remains close to that of the background matter.
- \( \Gamma < 1 \): The potential \( V_0 (1 - p^2)^{\gamma} \) and \( \cosh(p\alpha p) \) are attractive for \( \Gamma > 1 \) (known as tracking condition). This kind of behavior is called as slow roll behavior. In this case, during most of the cosmic evolution, scalar field density and its equation of state remains less than that of the dominant background matter.

From future work perspective, possible analytic solutions of these potentials can be done and using cosmological observations one can also put cosmological constraints on these various forms of potential discussed to get some new insights.

Conclusion
In the present work, we investigated various (power law, exponential and hyperbolic form) scalar field potentials under quintessence cosmological model to examine whether these potentials are showing tracking behavior or not. We analyzed this tracking behavior using tracking parameter for each potential and accordingly we get our results. It is found that among the four potentials used for examining tracking behavior, three (power law and exponential) are showing tracking properties and one (hyperbolic) is showing thawing property.
