Abstract: This preliminary study mainly compared the performance for predicting mild cognitive 10 impairment in Parkinson's disease (PDMCI) between single machine learning and hybrid machine 11 learning. This study analyzed 185 patients with Parkinson's disease (75 Parkinson's disease patients 12 with normal cognition, and 110 patients with PDMCI. PDMCI, an outcome variable, was divided 13 into "with PDMCI" and "with normal cognition" according to the diagnosis of the neurologist. This 14 study used 48 variables (diagnostic data), including motor symptoms of Parkinson's disease, non-15 motor symptoms of Parkinson's disease, and sleep disorders, as explanatory variables. This study 16 developed seven machine learning models using blending (3 hybrid models (polydot+C5.0, vanil-17 ladot+C5.0, and RBFdot+C5.0) and four single machine learning models (polydot, vanilladot, RBF-18 dot, and C5.0)). The results of this study showed that the RBFdot+C5.0 was the model with the best 19 performance to predict PDMCI in Parkinson's disease patients with normal cognition (AUC=0.88) 20 among the seven machine learning models. We will develop interpretable machine learning using 21 C5.0 in a follow-up study based on the results of this study. 22

Keywords:hybrid machine learning; blending approach; mild cognitive impairment in Parkinson's23disease; SVM; C5.024

## 1. Introduction

It has been reported that mild cognitive impairment (MCI), known as the preclinical 27 phase of dementia, may last up to seven years and appropriate therapeutic interventions 28 in the MCI stage can delay the progression to dementia approximately five years [1]. As 29 a result, many studies [2,3] have focused on detecting MCI, known as an intermediate 30 stage between normal aging and Alzheimer's dementia, as soon as possible. As longitu-31 dinal studies [4,5] on Parkinson's disease have reported that patients with Parkinson's 32 disease frequently suffer from cognitive impairment, recent studies [6,7] have paid more 33 attention to mild cognitive impairment in Parkinson's disease (PDMCI) as well as Alz-34 heimer's MCI. Although PDMCI occurs frequently in patients with Parkinson's disease, 35 the characteristics of PDMCI are known much less than those of Alzheimer's MCI and 36 those of vascular MCI. 37

Although a number of previous studies [8,9] have reported that the most critical 38 characteristic of PDMCI is executive function impairment due to frontal lobe dysfunction 39 found at an early stage, it is hard to detect it only with the degree of executive function 40 because early-stage MCI due to Alzheimer disease or vascular dementia shows executive 41 function impairment [10]. In particular, since Parkinson's disease progresses slowly and 42

3

symptoms appear little by little, patients and caregivers can perceive the cognitive problems caused by PDMCI as the cognitive frailty in the normal aging process. Therefore, it is hard to diagnose it early.

MCI is diagnosed based on an interview, evaluation of cognitive function through 4 standardized neuropsychological tests, and brain imaging. However, brain imaging has 5 limitations to be used for early diagnosis purposes because although it can detect the presence of cerebrovascular disease and brain atrophy, it can find them only when these symptoms are very advanced. Therefore, neuropsychological tests also evaluating cognitive 8 function are known to be effective screening tests for detecting MCI early [11]. 9

On the other hand, studies in the medical field have steadily predicted the risk prob-10 ability or high-risk groups of a disease using data mining in recent years [12,13]. However, 11 it is challenging to accurately predict diseases with single machine learning (learner). For 12 example, the artificial neural network technique has a limitation of not being able to ex-13 plain the derived results but it offers high prediction accuracy. On the other hand, the 14 decision tree technique allows clinicians to easily interpret the results derived from it, but 15 it is exposed to a higher overfitting risk than other machine learning algorithms such as 16 SVM, the results of it can be altered by the type and order of input variables, and the 17 accuracy of it can be lowered depending on them. 18

To overcome these limitations, a hybrid model combining Support Vector Machine 19 (SVM) and decision tree model has been used recently to develop a model that has higher 20 predictive power and explanatory power compared to single machine learning [14]. This 21 study developed a PDMCI predictive model considering health behaviors, environmental 22 factors, medical history, physical function, depression, and cognitive level using a hybrid 23 model combining C-SVM and C5.0 and provided baseline data for the prevention and 24 early management of Parkinson's dementia. This preliminary study mainly compared the 25 performance for predicting PDMCI between single machine learning and hybrid machine 26 learning. We will develop interpretable machine learning using C5.0 in a follow-up study 27 based on the results of this study. 28

#### 2. Method

#### 2.1. Data source

It is a secondary data analysis study that analyzed Parkinson's Disease Epidemiologic (Parde) Data after receiving an approval (No. KBN-2019-005) from the Distribution Committee and an approval (No. KBN-2019-1327) from the Research Ethics Review Committee of the Korea Centers for Disease Control and Prevention and National Biobank of Korea. The design and administration of Parde data are described in detail elsewhere [12]. This study analyzed 185 patients with Parkinson's disease (75 Parkinson's disease patients with normal cognition, and 110 patients with PDMCI. 31

#### 2.2. Measurement

PDMCI, an outcome variable, was divided into "with PDMCI" and "with normal 39 cognition" according to the diagnosis of the neurologist. This study used 48 variables (diagnostic data), including motor symptoms of Parkinson's disease, non-motor symptoms 41 of Parkinson's disease, and sleep disorders, as explanatory variables. 42

#### 2.3. Model blending based on machine learning

In this study, a PDMCI prediction model was developed using the blending approach (base model = SVM; meta model = C5.0). This study chose "C5.0" implemented by 46 Kuhn et al. (2013) for the decision tree algorithm and "kernel-based machine learning 47 (kernlab)" implemented by Karatzoglou et al. (2016) for the SVM to develop a PDMCI 48 predictive model. The kernlab algorithm includes a polynomial kernel function (polydot), 49

29

30

38

a linear kernel function (vanilladot), and a radial basis kernel function (RBFdot) that ena-1 ble nonlinear SVM analysis. This study developed seven machine learning models using 2 blending (3 hybrid models (polydot+C5.0, vanilladot+C5.0, and RBFdot+C5.0) and four 3 single machine learning models (polydot, vanilladot, RBFdot, and C5.0)). The structure of 4 the blending model in this study is presented in Figure 1. 5

Figure 1. The structure of the prediction for PDMCI

This study compared the predictive performance (general accuracy, F1-score, area under the curve (AUC), recall, precision) of these developed models using the 10-folds cross-validation method. This study assumed that a model with the highest AUC was the 12 best predictive performance. If the AUC was the same, a model with the highest F1-score 13 was assumed as the optimal model. 14

## 3. Results

#### 3.1. General characteristics of subjects

Among 185 patients with Parkinson's dementia, 59.5% (108 subjects) had PDMCI. 17 The results of chi-square test showed that PDMCI and Parkinson's disease patients with normal cognition had significantly different REM & RBD, Motor score of UPDRS, Total score of UPDRS, Global CDR, K-MoCA, K-MMSE, Sum of boxes in CDR, H&Y staging, K-20 IADL, and Schwab & England ADL (p<0.05). 21

## 3.2. Comparing the predictive performance of single model and that of blending model

The results of this study showed that the RBFdot+C5.0 was the model with the best 23 performance to predict PDMCI in Parkinson's disease patients with normal cognition 24 (AUC=0.88) among the seven machine learning models. The AUC and F1-scores of the 25 seven machine learning models analyzed in this study are presented in Figures 2 and 3, 26 respectively. 27

## 4. Conclusion

The results of this study showed that the RBFdot+C5.0 was the model with the best performance to predict PDMCI in Parkinson's disease patients with normal cognition 13

	(AUC=0.88) among the seven machine learning models. It is necessary to develop a cus- tomized screening program for detecting PDMCI in Parkinson's disease patients with nor- mal cognition early based on the results of this study. When developing a system to predict the morbidity of PDMCI from Parkinson's Dis- ease with Normal Cognition in the future, it will be possible to predict more accurately with the RBFdot+C5.0 model proposed in this study than single machine learning such as SVM. We will develop a machine learning model that can explain the characteristics of high PDMCI risk groups based on the results of this study.	1 2 3 4 5 6 7 8 9
