Non-selective beta-blockers as potential coadjuvants for prostate cancer treatment

Pharmaceutical Alone

Propranolol
Carvedilol
Atenolol
Metoprolol

Cisplatin
Flutamide

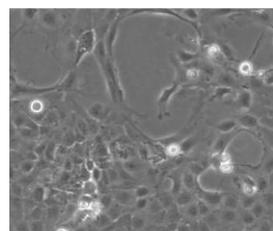

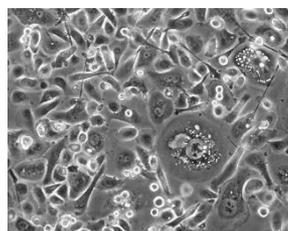

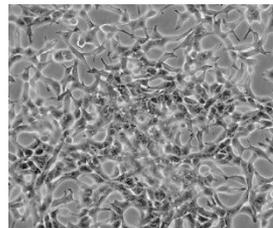

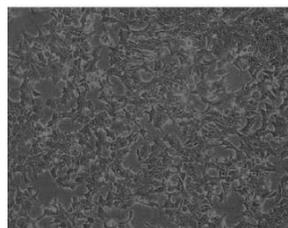

Combined Exposure

Propranolol + Cisplatin
Propranolol + Flutamide

Different Cells Lines

22Rv1

LNCaP

PC3

PNT-2

Effects

Cell Viability

Abstract: Prostate cancer is the third most diagnosed cancer worldwide, and the second cause of cancer death in men. The treatments currently available are not always effective. For that reason, new treatment options need to be explored, which can include the use of drugs, already clinically available, used for the treatment of other conditions, such as β -blockers. The present study aimed to explore the effects of several β -blockers and cytostatic drugs in prostate cancer cell lines (22Rv1, LNCaP and PC3) and a normal prostate cell line (PNT-2). Cells were exposed up to 72 h to increasing concentrations of propranolol, carvedilol (both non-selective β -blockers), atenolol, metoprolol (both β 1-blockers), cisplatin (a cytostatic drug) and flutamide (an androgen receptor blocker) and cell viability was assessed. The non-selective β -blockers selected, propranolol and carvedilol and cytostatic drugs displayed cytotoxic effect on all cell lines, while the β 1-blockers, metoprolol and atenolol did not alter significantly cells viability. Of the tested cell lines, 22Rv1 was the most sensitive to propranolol, carvedilol and cisplatin and PC3 was the most resistant. Therefore, sensitive line 22Rv1, resistant line PC3 and normal cell line PNT-2 were chosen for combined treatment between propranolol and cytostatic cisplatin and flutamide. Overall, the combined exposures revealed concentration dependent interactions between the cytostatic drugs and propranolol.

Introduction

Introduction

In this study:

The cytotoxicity of **β 1-blockers** (atenolol and metoprolol), **non-selective β -blockers** (carvedilol and propranolol), and **cytostatic drugs** (cisplatin and flutamide), was assessed **on prostate cancer cell lines** (22Rv1, LNCaP and PC3) and on a **normal prostate cell line** (PNT-2).

Effects of **binary combinations** of propranolol with cisplatin and propranolol with flutamide, were assessed on PNT-2, 22Rv1 and PC3 cells.

Conclusions

Non-selective β -Blockers (carvedilol and propranolol) showed higher cytotoxic effects than β 1-Blockers (atenolol and metoprolol) in all cell lines.

Non-selective β -Blockers, β 1-Blockers, Cisplatin and Flutamide cytotoxicity increased in a time-dependent manner.

22Rv1 was the most sensitive cell line to carvedilol, propranolol and cisplatin and PC3 the most resistant cell line.

The binary mixtures showed that at lower concentrations propranolol has a protective effect on PNT-2 (normal cell line), while for the same concentrations, the cytotoxic effects of cisplatin to the prostate cancer cell 22Rv1 was increased

Data suggest the potential role of propranolol on cancer treatment.
