**Abstract:** As urban areas expand, the focus on improving outdoor thermal comfort intensifies. This study generated Summer Discomfort Index (SDI) maps for Seville and Barcelona (Spain), as well as Tetuan (Morocco). SDI integrates temperature and humidity for accurate comfort assessment. Calculations involved substituting air temperature with land surface data from MODIS and incorporating humidity from weather stations, then comparing to Thermal Sensation Votes (TSV) gathered through surveys. The objective was to assess thermal comfort levels and explore the relationship between remotely sensed SDI and residents' reported perception. These detailed SDI maps offered crucial insights into summer thermal conditions, advancing urban climate studies and influencing urban planning, design, and well-being strategies.

**Keywords:** thermal comfort; thermal sensation vote; land surface temperature; Summer Discomfort Index

## 1. Introduction

In recent decades, urbanization has been a pivotal force, signifying the concentration of populations in cities and the consequential expansion of urban areas. This shift has emerged as a central topic in contemporary urban policy discussions, underlining its paramount importance [1]. Against the backdrop of global climate change and the swift pace of urban development, urban residents are confronted with progressively severe environmental challenges [2–4]. These challenges necessitate an urgent focus on enhancing outdoor thermal comfort to ensure the well-being of city dwellers.

Various thermal comfort indices are employed to assess the subjective perception of thermal comfort [5–8]. The Summer Discomfort Index (SDI) [9] is a modified version of Thom's Thermal Discomfort Index [10], it introduces a more visual approach to evaluating thermal comfort during warm seasons. Through user-friendly maps, it combines temperature and humidity factors, providing a clear measure of outdoor comfort levels. These maps can provide a valuable tool in urban planning and design.

## 2. Materials and Methods

Questionnaires were administered over various days in June 2022 in Tetuan, Morocco (35.5889° N, 5.3626° W), and on distinct days of June 2023 in Seville (37.3891° N, 5.9845° W) and Barcelona (41.3874° N, 2.1686° E), Spain.

**Figure 1.** Study areas Tetuan, Morocco and Seville, Barcelona, Spain.

All questionnaires included various personal and environmental questions. For sensation vote, it employed ASHRAE'S [5–8] seven-point scale for evaluating thermal comfort. Consequently, thermal sensation votes (TSV) were calculated based on the following rating: -3 for feeling cold, -2 for feeling cool, -1 for feeling slightly cool, 0 for feeling comfortable, 1 for feeling slightly warm, 2 for feeling warm, and 3 for feeling hot.

The Summer Discomfort Index (SDI) in this study was derived by leveraging the observed correlation between air temperature and land surface temperature. This correlation enabled the establishment of a precise linear regression equation, pivotal in calculating SDI values. This equation was then seamlessly integrated into the SDI maps, ensuring a dependable and accurate portrayal of thermal discomfort across our selected locations. This process was underpinned by meticulous data acquisition over a comprehensive period of three decades, drawing from four distinct outdoor thermal comfort databases covering ten cities with diverse geographical and climatic profiles. In instances where air temperature data was not directly accessible, we turned to trustworthy weather stations to supplement our dataset. Additionally, land surface temperature data for each location was sourced from the Moderate Resolution Imaging Spectroradiometer (MODIS), further enhancing the robustness and comprehensiveness of our thermal environment representation. The main daily humidity data, derived from reputable weather stations, was used as the second component in the calculation of SDI.

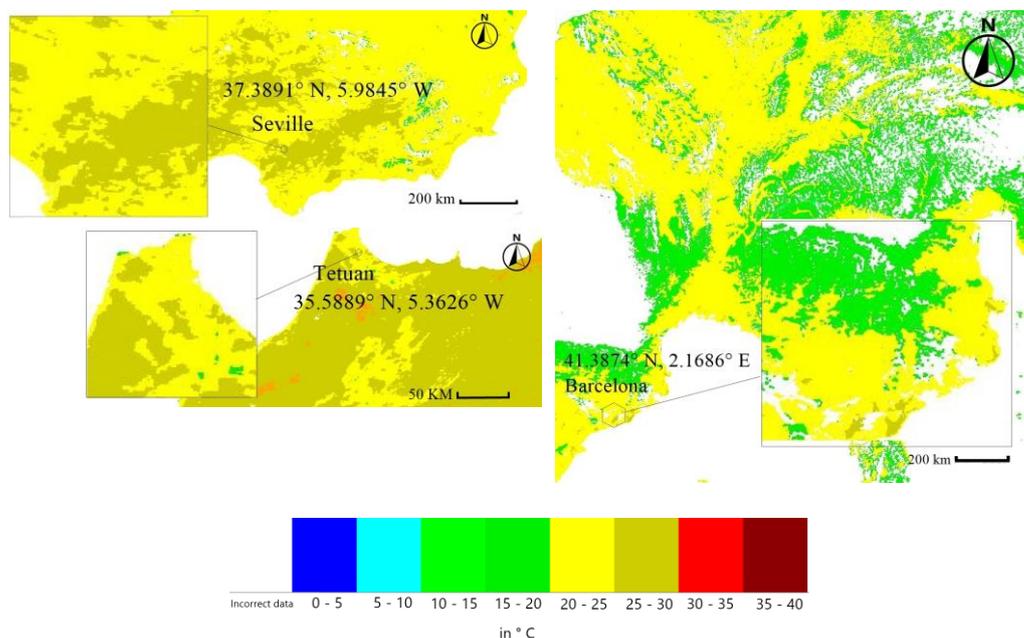

### 3. Results

In Tetuan, Morocco, we observed the lowest temperatures coupled with the highest levels of humidity. In stark contrast, Seville exhibited the highest temperatures but experienced the lowest humidity levels. Barcelona fell in between, ranking second in both temperature and humidity (Table 1).

**Table 1.** Average Thermal Sensation Vote (TSV), Temperature, and Humidity in Studied Cities.

City, Country	Days	Mean TSV	Mean Temperature in °C	Mean Humidity in %
Tetuan, Morocco	1 June 2022	1.44	26.0	57
	3 June 2022	0.43	25.0	56
	13 June 2022	0.32	24.9	64
Seville, Spain	1 June 2023	0.14	26.1	39
	6 June 2023	1.29	31.8	25
Barcelona, Spain	15 June 2023	1.26	28.8	46

Furthermore, our analysis using the Summer Discomfort Index (SDI) maps on the same date revealed insightful patterns. The high temperatures in Seville, coupled with the elevated humidity levels in Tetuan, rendered both cities slightly warmer than Barcelona. Interestingly, Barcelona’s SDI map indicated localized spots that offered a marginally more comfortable thermal experience compared to the other cities.

**Figure 2.** Summer discomfort index map (SDI) of the three different cities on 15 June 2023.

### 4. Discussion

The comparative analysis of Tetuan, Seville, and Barcelona provides valuable insights into the diverse thermal environments within cities classified under the same Köppen climate type (Csa). Notably, Tetuan, Morocco exhibited the lowest temperatures in the studied period along with the highest humidity levels, while Seville, Spain experienced elevated temperatures and lower humidity levels and Barcelona fell in between, ranking second in both temperature and humidity. These findings emphasize the nuanced microclimatic differences that significantly influence the thermal experiences of residents and visitors.

The observed variations in thermal conditions align with the geographic and climatic characteristics of each city. Tetuan, located in northern Morocco, experiences the moderating influence of the Mediterranean Sea, leading to milder temperatures but higher humidity levels. Seville, situated inland in southern Spain, is characterized by hot, dry summers typical of continental climates. Barcelona, also along the Mediterranean coast, benefits from a maritime influence, resulting in relatively moderate temperatures and humidity levels.

The Summer Discomfort Index (SDI) further corroborates our findings. Both Tetuan and Seville, with their combination of high temperatures and humidity levels, exhibited slightly higher discomfort levels compared to Barcelona. Interestingly, Barcelona's SDI map revealed localized areas that offered a slightly more comfortable thermal experience. This suggests the presence of microclimatic variations within the city, influencing the perceived thermal comfort of its inhabitants.

## 5. Conclusions

The characteristics of the environment, an individual's capacity for adaptation, and the insulation of one's clothing are among the variables that affect thermal sensation variations. Research and planning are made easier by the objective depiction of thermal conditions provided by visual maps. The Summer Discomfort Index (SDI) brought attention to differences in thermal perception among the cities and emphasized the value of using both objective measurements and subjective assessments.

Additionally, the cities exhibited distinct temperature and humidity profiles. In Tetuan, Morocco, the lowest temperatures were observed with high humidity, while Seville experienced high temperatures with low humidity. Barcelona ranked in between. Despite sharing a Köppen climate classification (Csa), significant microclimatic differences were observed, underlining their impact on residents' experiences.

In summary, our findings demonstrate the intricate interplay between temperature, humidity, and thermal comfort in these Mediterranean cities. These nuanced differences should be carefully considered in urban planning and design to create spaces that prioritize the well-being and comfort of inhabitants.
