Abstract: Parkinson's disease (PD) is the second most common neurodegenerative chronic disorder in the older people, caused by the loss of dopaminergic neurons in the brain, which leads to the dopamine depletion. Among its symptoms (resting tremor, rigidity, dementia...). Monoamine oxidase B (MAO-B) is a key enzyme in PD. The inhibition of it increases the level of dopamine in the brain by preventing its degradation, especially in the early stages of the disease. In the present work, we combined molecular docking with ADME analysis of a new class of ten derivatives of indanone in order to reduce the metabolic depletion of dopamine through inhibiting the MAO-B. A molecular docking study was performed to clarify bonding modes and affinities between the active site residues of MAO-B with the new class derivatives of indanone, followed by the ADME prediction to check the druglikeness properties of the best ligands obtained using the method above. Molecular docking results show that the ligands: L3 and L5 present a high negative score energy (−8.809 kcal/mol, −9.276 kcal/mol) respectively with a good RMSD values (1.419 Å, 1.560 Å) respectively. Moreover, the ADME prediction gave promising results that those ligands have an oral bioavailability and a high level of gastrointestinal absorption, which means they can be good inhibitors against Parkinson's disease.

Keywords: Parkinson's disease; MAO-B; indanone derivatives; molecular docking; ADME

1. Introduction

The prevalence of neurodegenerative disorders (NDs) is increasing, making them a global health concern of significant proportions. The aging population, especially in wealthy countries, has seen an elevation in the rate at which chronic diseases are spreading in recent years [1]. Parkinson's disease (PD) is the second most common neurodegenerative disease [2], caused by the death of dopaminergic neurons in the substantia nigra, which depletes dopamine. Motor symptoms include resting tremor and rigidity, while non-motor symptoms include disorganization and coherence distortion [3]. MAO-B (monoamine oxidase B) is major target in PD. Inhibition of this enzyme boosts dopamine levels in the brain by preventing its breakdown, particularly in the early stages of illness [2].

This research is a structure-based drug design investigation of a new family of indanone derivatives to diminish the metabolic depletion of dopamine by inhibiting the Parkinson's disease-related enzyme MAO-B.

2. Material and Methods

In order to understand the interactions and affinities between this new class of derivatives and the active site residues of MAO-B target, we conduct a molecular docking analysis using the following parameters: the scoring energy, the RMSD value of the generated complexes, and the interaction kinds and distances. A computation of ADME-T characteristics was performed to investigate the drug-likeness proprieties of the best compounds generated using molecular modeling simulation.

MAO-B (PDB ID: 2C65) crystal structures was retrieved from RCSB Database (www.rcsb.org/pdb). Compound structures were designed using the ChemDraw professional 16.0 program; they were then optimized using the Molecular Operating Environment (MOE) software (Version 2014.09) and the semi-empirical energy function AM1.

To facilitate the molecular docking process, cofactors, ions, and glycols have been removed from the chosen enzyme. The compounds were designed to be flexible, whereas the target was inflexible. All complexes' molecular docking data were acquired using the same software. The ADME calculations were performed using the SWISSADME web-based program.

3. Results and Discussion

Table 1. S-score (Energy) and interactions between compounds and the active site residues of hMAO-B target.

Ligands	S-Score (kcal/mol)	RMSD (Å)	Bonds between Atoms and hMAO-B (PDB ID:2C65) Active Site Residues				
			Atome of Ligand	Involved Receptor Atoms	Involved Receptor Residues	Type of Interaction bond	Distance (Å)
L3	-8.809	1.419	6-ring	CA	ILE199(A)	Pi-H	4.60
L5	-9.276	1.560	/	/	/	/	/

Table 2. ADME properties of the best ligands.

Ligands	Physico-Chemical Properties				Lipophilicity		Pharmacokenitics		
	TPAS(Å)	MW (g/mol)	Num Rotatble Bonds	Num H-Bond Acceptors	Num H-Bond Donors	MLOGP	WLOGP	GI Absorption	BBB Permeant
L3	29.54	245.32	4	3	0	1.83	1.91	High	Yes
L5	29.54	273.37	5	3	0	2.33	2.69	High	Yes

Table 3. Druglikeness, Bioavailability Score and Synthetic accessibility of the best ligands.

Ligands	Druglikeness				Bioavailability Score	Synthetic Accessibility
	Lipinski	Ghose	Veber	Egan		
L3	Yes 0 violation	Yes	Yes	Yes	0.55	2.09
L5	Yes 0 violation	Yes	Yes	Yes	0.55	2.30

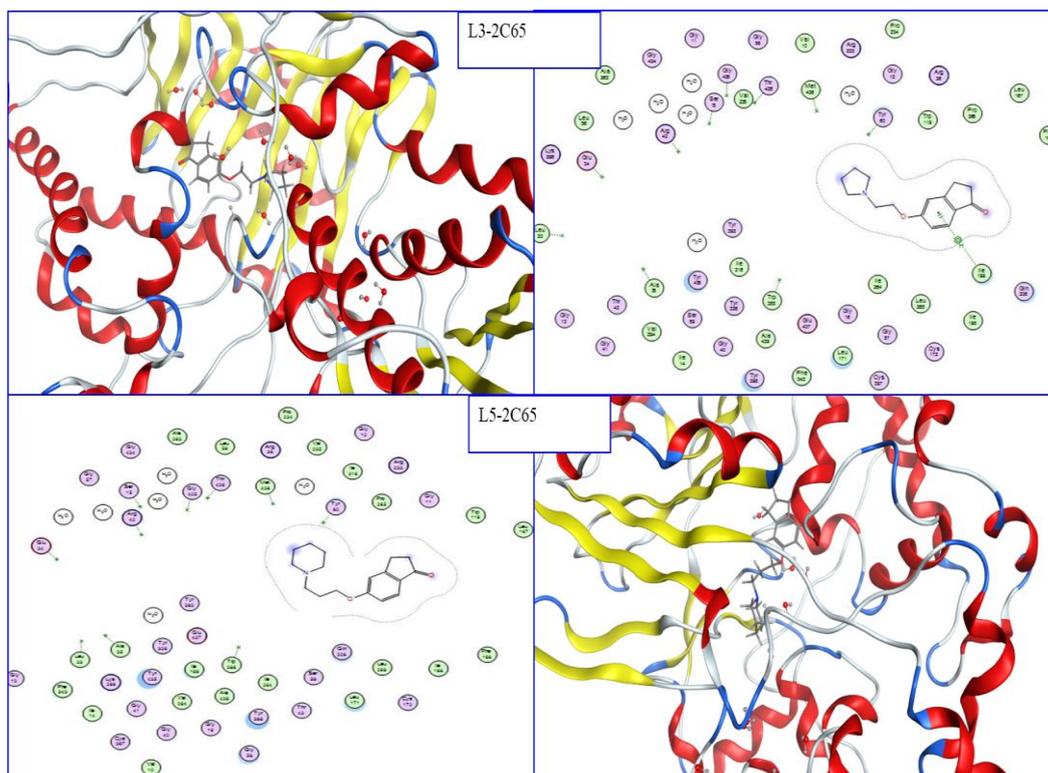

Figure 3. 2D and 3D interaction of the best compounds into MAO-B.

According to the results of molecular docking studies, the formation of the complexes that are the most stable occurs when molecules L3: 5-(2-(Pyrrolidin-1-yl)ethoxy)-2,3-dihydro-1H-inden-1-one and L5: 5-(3-(Piperidin-1-yl)propoxy)-2,3-dihydro-1H-inden-1-one are incorporated into MAO-B (PDB: 2C65). Both L3 and L5 have negative energy scores of -8.809 and -9.276 (kcal/mol) and good RMSD values of 1.419 (Å), 1.560 (Å) respectively, have passed all drug-likeness rules without any violations, and have a bioavailability score of 0.55, which indicates that they have excellent pharmacokinetic characteristics and good oral and gastrointestinal absorption, which means they are also considered excellent candidates for further study. The low values of the synthetic accessibility score (SA score) for these ligands (SA2) provide additional evidence for the ease with which they can be synthesized.

4. Conclusions

In light of these findings and due to their low negative score energy, MAO-B-L3 and MAO-B-L5 complexes are the most stable.

Compounds L1: 6-(2-(Pyrrolidin-1-yl)ethoxy)-2,3-dihydro-1H-inden-1-one and L2: 6-(3-(Piperidin-1-yl)propoxy)-2,3-dihydro-1H-inden-1-one were also shown to be pharmacologically active, suggesting they could be useful as lead candidates for the cure or inhibition of Parkinson's disease.
