**Abstract:** Air pollution is a serious issue that affects many parts of the world, Southeast Asia in particular. Nitrogen dioxide, particulate matter, sulfur oxides, and other emissions have negative impacts on human health as well as overall environmental quality. The major sources in Thailand are open burning and fossil fuel combustion, both in vehicles and power generation. Given increasing actual and projected GDP growth, subsequent increases in energy consumption are inevitable. The power generation system must grow and expand as well to meet changes in demand from industrial, commercial, and residential customers. The Ministry of Energy of Thailand has published the Power Development Plan 2015 (PDP 2015) to outline policies and goals of the growing power generation and transmission systems throughout the nation. Notably, the plan involves increasing the use of coal-fired generation. Using both the Greenhouse Gas and Air Pollution Interactions and Synergies Model (GAINS) and the Comprehensive Air Quality Model with Extensions (CAMx), we have compared two different emissions scenarios: one with standard emission control technology, and another with maximum emission controls. The effectiveness of emission control technology varied by region and pollutant. The greatest increase in air quality was located around Rayong province of the eastern region. For PM10 in the north, however, emission control technologies did little to increase air quality because the main source of pollutant, biomass burning, was left unabated. This forecast of air quality can show possible impacts from future air quality in Thailand and regions that may benefit from added emission control technology in the future.

# Thai Power Development Plan 2015

- Published in 2015, projected growth of power sector to 2036
- Highlights changes in fuel share (coal, natural gas, etc.)
- 3 mains goals
  - Increase energy security
  - Maintain reasonable cost to consumer
  - Reduce Greenhouse Gas emissions

# Future Study

- Solve CAMx pollution modelling discrepancy in the SPEN region
- Conduct regional modelling with a resolution better than 12km by 12km
- Use BenMAP to predict DALY from concentrations
- Designing scenarios with wider ranges of emissions control technologies
- Interchanging fuel types for optimal air quality
