- There exist two variant for interpretation of relation between time derivative and e-folding number derivative:

$$\textcircled{1} \quad \frac{d}{dt} = H \frac{d}{dN_e} \text{ and}$$

$$\textcircled{2} \quad \frac{d}{dt} = -H \frac{d}{dN}.$$

In the case of the first type formulation, the inflation interval in the e-folding formulation is  $-65 < N_e < 0$ .

In the case of the second type formulation, inflation interval in e-folding formulation  $0 < N < 65$ .

The second formation was applied in cosmological attractor approximation <sup>4</sup> and we follow to the second formulation with

$$N = -\ln\left(\frac{a}{a_{end}}\right).$$

- We construct a gravity model with the Gauss-Bonnet term multiplied to a function of a scalar field which allows to reconstruct expressions for spectral index and tensor-to-scalar ratio from cosmological attractor models in the slow-roll regime. This model includes several constants with variable values. Therefore, we construct a family of models with different values of the constants. We consider the scalar power spectral amplitude and estimate possible values of model parameters using modern observational data .

- 1 We reformulate the problem of the slow-roll regime in Einstein-Gauss-Bonnet gravity in terms of e-folding numbers
- 2 We apply our reformulation to construct model with variable values of parameters which leads to the cosmological attractor approximation for inflationary parameters.
- 3 To satisfy observational data we introduce restriction to model parameters.
- 4 In Conclusions we summaries our results.

# Einstein-Gauss-Bonnet gravity

- We consider the model with the Gauss-Bonnet term multiplied to a function of the scalar field  $\phi$ :

$$S = \int d^4x \sqrt{-g} \left[ \frac{R}{2} - \frac{\partial^\nu \phi \partial_\nu \phi}{2} - V(\phi) - \frac{\xi(\phi)}{2} \mathcal{G} \right], \quad (3)$$

where  $\mathcal{G} = R_{\mu\nu\rho\sigma} R^{\mu\nu\rho\sigma} - 4R_{\mu\nu} R^{\mu\nu} + R^2$ .

- Application of the variation principle leads to the following system of equations in spatially flat FLRW metric with  $ds^2 = -dt^2 + a^2(t)(dx^2 + dy^2 + dz^2)$ :

$$6H^2 = \dot{\phi}^2 + 2V + 24\xi\dot{H}^3, \quad (4)$$

$$2\dot{H} = -\dot{\phi}^2 + 4\ddot{\xi}H^2 + 4\dot{\xi}H(2\dot{H} - H^2), \quad (5)$$

$$\ddot{\phi} + 3H\dot{\phi} + V_{,\phi} + 12\xi_{,\phi}H^2(\dot{H} + H^2) = 0, \quad (6)$$

where  $H = \dot{a}/a$ , the dot means the derivative of time:  $\dot{A} = dA/dt$ .

# Slow-roll regime in Einstein-Gauss-Bonnet gravity

- We consider the model with the Gauss-Bonnet term multiplied to a function of the scalar field in FLRW metric in the slow-roll regime <sup>6</sup>:

$$\dot{\phi}^2 \ll V, \quad |\ddot{\phi}| \ll 3H|\dot{\phi}|, \quad 4|\dot{\xi}|H \ll 1, \quad |\ddot{\xi}| \ll |\dot{\xi}|H, \quad (7)$$

in which of the equations of motion are:

$$H^2 \simeq \frac{V}{3}, \quad \dot{H} \simeq -\frac{\dot{\phi}^2}{2} - 2\dot{\xi}H^3, \quad \dot{\phi} \simeq -\frac{V_{,\phi} + 12\xi_{,\phi}H^4}{3H}. \quad (8)$$

- The slow-roll parameters are:

$$\epsilon_1 = -\frac{\dot{H}}{H^2}, \quad \epsilon_{i+1} = \frac{d \ln |\epsilon_i|}{d \ln a}, \quad i \geq 1, \quad (9)$$

$$\delta_1 = 4\dot{\xi}H, \quad \delta_{i+1} = \frac{d \ln |\delta_i|}{d \ln a}, \quad i \geq 1. \quad (10)$$

---

<sup>6</sup>Z. Guo and D. J. Schwarz, Phys. Rev. D **81** (2010), 123520 [arXiv:1001.1897 [hep-th]].

# Cosmological attractor generalization

- To get cosmological attractor generalization we consider the model in slow-roll regime using the e-folding number representation and designation  $A' = dA/dN$ :

$$(\phi')^2 \simeq \frac{V'}{V} + \frac{4}{3}\xi'V = \frac{(H^2)'}{H^2} + 4H^2\xi'. \quad (11)$$

- We present the first slow-roll parameters in terms of  $H^2$ ,  $\xi$ :

$$\epsilon_1 = \frac{1}{2} \frac{(H^2)'}{H^2}, \delta_1 = -4H^2\xi'. \quad (12)$$

- The second slow-roll parameters are related with first slow-roll parameters:

$$\epsilon_2 = -\epsilon_1'/\epsilon_1, \quad \delta_2 = -\delta_1'/\delta_1. \quad (13)$$

- The slow-roll approximation requires  $|\epsilon_i| \ll 1$ ,  $|\delta_i| \ll 1$ .

- The numbers of inflation scenarios in Einstein-Gauss-Bonnet can be restricted such as the speed of sound should be real <sup>7</sup>.
- However there is a wonderful properties : In slow-roll regime the speed of sound is real. Such as the square of speed of sound can be presented in the form  $c_A^2 = 1 + \Delta c_A^2$ , where

$$\Delta c_A^2 = -\frac{2\delta_1^2\epsilon_1}{3\delta_1^2 + 2(2\epsilon_1 - \delta_1)(1 + \delta_1)}. \quad (14)$$

In general case of slow-roll regime

$$\Delta c_A^2 \simeq -(\delta_1^2\epsilon_1)/(2\epsilon_1 - \delta_1) \ll 1.$$

If  $2\epsilon_1 \approx \delta_1$ , then  $\Delta c_A^2 \simeq -2\epsilon_1/3 \ll 1$ . Thus, we can conclude  $c_A^2 > 0$  in slow-roll regime.

---

<sup>7</sup>G. Hikmawan, J. Soda, A. Suroso and F. P. Zen, Phys. Rev. D **93** (2016) no.6, 068301 [arXiv:1512.00222 [hep-th]]

S. Odintsov and V. Oikonomou, Phys. Lett. B **805** (2020), 135437 [arXiv:2004.00479 [gr-qc]]

- The spectral index of scalar perturbations and the tensor-to-scalar ratio can be presented in terms e-folding numbers derivatives:

$$n_s = 1 - 2\epsilon_1 + \frac{r'}{r}, \quad (15)$$

$$r = 8|2\epsilon_1 - \delta_1| = 8 \left( \frac{(H^2)'}{H^2} + 4H^2\xi' \right) = 8(\phi')^2. \quad (16)$$

using  $\epsilon_2 = -\epsilon_1'/\epsilon_1$ ,  $\delta_2 = -\delta_1'/\delta_1$ .

- The expression for amplitude in the leading order is :

$$A_s \simeq \frac{2H^2}{\pi^2 r} \simeq \frac{V}{6\pi^2 U^2 r}. \quad (17)$$

# Generalization of the cosmological attractor method

- Accordingly to inflationary parameters of cosmological-attractor models without the Gauss-Bonnet term spectral index includes only logarithmic derivative of tensor-to-scalar ratio

$$\frac{r'}{r} = -\frac{2}{N + N_0}, \quad \text{and} \quad n_s \approx 1 + \frac{r'}{r}. \quad (18)$$

in the leading order of  $1/N$  approximation.

- The model without the Gauss-Bonnet term and exponential potential leading to cosmological-attractor prediction was considered in <sup>8</sup>
- We generalize this model to the Einstein-Gauss-Bonnet gravity.

---

<sup>8</sup>V. Mukhanov, Eur. Phys. J. C **73** (2013), 2486 [arXiv:1303.3925 [astro-ph.CO]]

# Exponential form

To generalize cosmological attractor approximation to inflationary models with the Gauss-Bonnet term we compare (16) with (2):

$$\frac{r}{8} = \frac{(H^2)'}{H^2} + 4H^2\xi' = \frac{3C_\alpha}{2(N + N_0)^2}. \quad (19)$$

For simplicity we suppose that all terms in this equation are proportional to  $1/(N + N_0)^2$  and get the same approximation of slow-roll parameter  $\epsilon_1$  in leading  $1/N$  order:

$$H^2 = H_0^2 \exp\left(-\frac{3C_\beta}{2(N + N_0)}\right), \quad \xi = \xi_0 \exp\left(\frac{3C_\beta}{2(N + N_0)}\right), \quad (20)$$

where  $C_\beta$  is a constant. We substitute (20), (20) to (19) and get:

$$\frac{r}{8} = \frac{3C_\beta}{2(N + N_0)^2} (1 - 4\xi_0 H_0^2), \quad (21)$$

fixing a relation between  $C_\alpha$  and  $C_\beta$ :

$$C_\beta = \frac{C_\alpha}{1 - 4\xi_0 H_0^2}, \quad H_0^2 \neq \frac{1}{4\xi_0}. \quad (22)$$

Accordingly (16) the derivative of field is related with e-folding number:

$$(\phi')^2 = \frac{3C_\alpha}{2(N + N_0)^2}; \quad \phi' = \frac{\omega_\phi \sqrt{\frac{3C_\alpha}{2}}}{N + N_0}, \quad \omega_\phi = \pm 1 \quad (23)$$

from here

$$\phi = \omega_\phi \sqrt{\frac{3C_\alpha}{2}} \ln \left( \frac{N + N_0}{N_\phi} \right), \quad N + N_0 = N_\phi \exp \left( \omega_\phi \sqrt{\frac{2}{3C_\alpha}} \phi \right). \quad (24)$$

Using (8), (20) and (24) we construct family of the models with the Gauss-Bonnet interaction and potential with variable parameter  $C_\alpha$ :

$$V = 3H_0^2 \exp \left( -\frac{3}{2} \frac{C_\beta}{N_\phi} \exp \left( -\omega_\phi \sqrt{\frac{2}{3C_\alpha}} \phi \right) \right), \quad (25)$$

$$\xi = \xi_0 \exp \left( \frac{3}{2} \frac{C_\beta}{N_\phi} \exp \left( -\omega_\phi \sqrt{\frac{2}{3C_\alpha}} \phi \right) \right) \quad (26)$$

leading to appropriate inflationary scenarios. This model is generalization of the general relativity model obtained in <sup>9</sup>

<sup>9</sup>V. Mukhanov, Eur. Phys. J. C **73** (2013), 2486 [arXiv:1303.3925 [astro-ph.CO]]

# Inflationary parameters in terms of field

To estimate the inflationary parameters (tensor-to-scalar ratio, spectral index of scalar perturbations) for both models we use following expressions

$$r = 8Q^2, \quad n_s = 1 - Q \frac{V_{,\phi}}{V} + 2Q_{,\phi}, \quad Q = V_{,\phi}/V + 4\xi_{,\phi} V/3. \quad (27)$$

For the exponential models we get

$$r = \frac{64 (1 - 4H_0^2 \xi_0)^2}{3C_\alpha} \left( \exp \left( -\omega_\phi \sqrt{\frac{2}{3C_\alpha}} \phi \right) \right)^2,$$
$$n_s = 1 - \frac{8 \exp \left( -\omega_\phi \sqrt{\frac{2}{3C_\alpha}} \phi \right) \left( 1 + \exp \left( -\omega_\phi \sqrt{\frac{2}{3C_\alpha}} \phi \right) \right) (1 - 4H_0^2 \xi_0)}{3C_\alpha}$$

# Inflationary parameters in terms of e-folding number

Now we apply relation between field and e-folding number (24) and obtain:

$$r = \frac{64 (1 - 4H_0^2 \xi_0)^2}{3C_\alpha} \left( \frac{N_\phi}{N + N_0} \right)^2 \quad (28)$$

$$n_s = 1 - \frac{8 (1 - 4H_0^2 \xi_0)}{3C_\alpha} \left( \frac{N_\phi}{N + N_0} + \left( \frac{N_\phi}{N + N_0} \right)^2 \right) \quad (29)$$

To present this expressions in more regular form we apply (22)

$$r = \frac{64 N_\phi^2 (1 - 4H_0^2 \xi_0)}{3C_\beta (N + N_0)^2} = \frac{64}{3} \frac{C_\alpha N_\phi^2}{(N + N_0)^2} \quad (30)$$

$$n_s = 1 - \frac{8}{3C_\beta} \left( \frac{N_\phi}{N + N_0} + \left( \frac{N_\phi}{N + N_0} \right)^2 \right) \quad (31)$$

Substituting  $N_\phi = \frac{3C_\beta}{4}$ ,  $C_\beta = 1$  we get

$$r = \frac{64N_\phi^2 (1 - 4H_0^2 \xi_0)}{3C_\beta (N + N_0)^2} = \frac{12C_\alpha}{(N + N_0)^2} \quad (32)$$

$$n_s = 1 - \left( \frac{2}{N + N_0} + \frac{9}{16(N + N_0)^2} \right) \quad (33)$$

Evidently that in the beginning of inflation then  $N + N_0 \approx 60$  we can roughly suppose

$$r \approx \frac{12C_\alpha}{(N + N_0)^2}, \quad n_s \approx 1 - \frac{2}{N + N_0} \quad (34)$$

The obtained approximations are coincide with inflationary parameters of attractors approximation and in the case of  $C_\alpha \approx 1$  with parameters of  $R^2$  inflation. The case  $C_\alpha = 1$  leads to switch of Gauss-Bonnet interaction and to coinciding with exponential scenario early obtained in Einstein Gravity.

In the large field  $\phi$  approximation the expressions for  $r$  and  $\tilde{r}$  are coincide up to second order, the expressions for  $n_s$  and  $\tilde{n}_s$  are coincide up to first order of  $\exp\left(-\sqrt{\frac{2}{3C_\alpha}}\phi\right)$ . The precision coincides with sensibility of cosmological attractor approximation (2). To satisfy the proposal sensibility we can write

$$n_s \simeq 1 + \frac{8(4H_0^2\xi_0 - 1)}{3C_\alpha} \exp\left(-\sqrt{\frac{2}{3C_\alpha}}\phi\right),$$

$$r \simeq \frac{64(4H_0^2\xi_0 - 1)^2}{3C_\alpha} \exp\left(-2\sqrt{\frac{2}{3C_\alpha}}\phi\right).$$

Accordingly to (22) these relations can be presented in the forms:

$$n_s \simeq 1 - \frac{2}{N_\phi} \exp\left(-\sqrt{\frac{2}{3C_\alpha}}\phi\right),$$

$$r \simeq \frac{12C_\alpha}{N_\phi^2} \exp\left(-2\sqrt{\frac{2}{3C_\alpha}}\phi\right)$$

which are fully correspond to (2).

# Restriction to the model parameters

- Accordingly to the Planck data
  - value of scalar spectral index and the restriction to tensor-to-scalar ratio are:

$$n_s \approx 0.965 \pm 0.004 \text{ and } r < 0.056$$

- value of scalar power spectrum amplitude is  $A_s \approx 2 \cdot 10^{-9}$ .
- The considered inflationary models with the Gauss-Bonnet interaction can be presented more precisely, namely, to satisfy condition  $\epsilon_1(N \simeq 0) \approx 1$  we should suppose  $N_0 = \sqrt{3C_\beta/4}$ .

Accordingly to (2) the highest value of constant  $C_\alpha$  is related with modern observations restriction to the tensor-to-scalar ratio  $r$  and the value of e-folding number at the beginning of inflation. At the same time a start point of inflation defines the value of spectral index of scalar perturbations.

We numerically estimate the value of the model parameters using (2) and supposing that the inflation begin:

- 1 at  $N \approx 55 - N_0$  before the end of inflation:  $n_s \approx 0.964$  and  $0 \leq C_\alpha < 14.1$ ;
- 2 at  $N \approx 60 - N_0$  before the end of inflation:  $n_s \approx 0.967$  and  $0 \leq C_\alpha < 16.7$ ;
- 3 at  $N \approx 65 - N_0$  before the end of inflation:  $n_s \approx 0.969$  and  $0 \leq C_\alpha < 19.6$ .

To get expression for scalar power spectrum amplitude we substitute (19) and (20) to (17):

$$A_s \simeq \frac{H_0^2(N + N_0)^2}{6\pi^2 C_\alpha} \exp\left(-\frac{3C_\beta}{2(N + N_0)}\right) \quad (35)$$

$$= \frac{H_0^2(N + N_0)^2}{6\pi^2 C_\alpha} \exp\left(-\frac{2N_0^2}{N + N_0}\right), \quad (36)$$

from where

$$\frac{H_0^2}{C_\alpha} = \frac{6\pi^2 A_s}{(N + N_0)^2} \exp\left(\frac{2N_0^2}{N + N_0}\right). \quad (37)$$

To estimate  $H_0^2/C_\alpha$  we suppose  $N_0 \approx 1$  in three cases:

- 1 if the start point of inflation  $N \approx 54$ , then  $H_0^2/C_\alpha \approx 4.09 \cdot 10^{-11}$
- 2 if the start point of inflation  $N \approx 59$ , then  $H_0^2/C_\alpha \approx 3.40 \cdot 10^{-11}$
- 3 if the start point of inflation  $N \approx 64$ , then  $H_0^2/C_\alpha \approx 2.90 \cdot 10^{-11}$

# Conclusion

- We get the generalization to the cosmological attractor of exponential form to gravity with the Gauss-Bonnet term. The generalization lead to analytical expressions for inflationary parameters coinciding with inflationary parameters of cosmological attractor models in the leading order approximation.
- Within the framework of the model we obtain an analytical expression for scalar power spectrum amplitude. We estimate the models constants using observation data.
- We considered the exponential inflationary scenario in Einstein-Gauss-Bonnet gravity and get that the direct calculations of spectral index for this model includes second order inverse e-folding number term. However such as in the beginning of inflation  $N + N_0 \approx 60$  this term is negligible in relation to first order inverse e-folding number term. And roughly we can suppose that the cosmological attractor approximation for inflationary parameters are satisfied for considering model. Moreover the switch of Gauss-Bonnet interaction can leads  $R^2$  gravity prediction for inflationary parameters in leading order approximation in inverse e-folding number.
